A name given by naturalists to the animals of the class Spongia, sub-kingdom Protozoa. Sponges are compound Protozoa, their living parts consisting of an aggregation of protoplasmic units. The skeleton may be horny, flinty, or limy. (See **Spongida**.) In common usage the term is employed to designate the fibrous framework of sponges, as sold in our shops. This framework is soft, light, and porous, easily compressible, readily imbibing fluids, and thereby distending, and as readily giving them out again upon compression. The domestic uses of sponge are familiar to all. It is indispensable to the surgeon. Burnt sponge was formerly a valued remedy for scrofulous diseases and goitre; but iodine and bromine, from which it derived all its value, are now administered in other forms. Mattresses, &c., are stuffed with sponge; and it is also employed as a filter and as a polishing material for fine surfaces. Sponges are usually prepared before they come into the market, by being beaten and soaked in dilute muriatic acid, with a view to bleach them and dissolve any adherent portions of carbonate of lime. The kinds fit for use are found in the seas of warm climates. Two species are chiefly brought from the Levant, and a coarse one from the West Indies and the coast of Florida.—2. Spongida, Spongidae (spunj'i-da, spunj'idē), *n. pl.* An order of Protozoa or lowest animals, class Rhizopoda, sometimes elevated into a distinct class. The members are composed of two elements, an internal supporting framework or skeleton, and a soft gelatinous investing substance called *sarcode*, or 'flesh.' The framework consists of the horny, reticulated, elastic fibres of a substance called *keratode*, which interlace in every direction, strengthened by calcareous, or, more generally, by siliceous spicules. This framework is the sponge of commerce. On examining it we find it filled with pores, having larger openings or canals at wider distances, called *ocula* or vents. The sponge-flesh investing this framework is composed of an aggregation of organless, protoplasmic, and amoebiform bodies, some ciliated and others capable of emitting pseudopodia. A constant circulation of water goes on in the living sponge, the currents being drawn in by the pores and expelled by the oscula by means of vibratile cilia lodged in cells or chambers situated beneath the superficial layer, and by this circulation the animal is nourished. Reproduction takes place both by gemination and true ova. In the skeletons of the true calcareous and siliceous sponges the keratode is wanting. Sponges have been classified into three groups: (a) Myxospongiae, in which no skeleton of any kind exists. (b) Calci-spongiae, or limy sponges, which have no horny skeleton, but are composed of limy spicules. (c) Fibrospongiae, or those in which a fibrous skeleton exists, strengthened usually by flinty spicules.

Springs are used for various purposes—diminishing concussion, as in carriages; for motive power, acting through the tendency of a metallic coil to unwind itself, as in clocks and watches; or to communicate motion by sudden release from a state of tension, as the bow to the arrow, the spring of a gun-lock, &c.; others are employed to measure weight and other force,

as in the spring-balance, as regulators to control the movement of wheel-works, &c. 5. Any active power; that by which action or motion is produced or propagated.

6. A natural fountain of water; an issue of water from the earth, or the basin of water at the place of its issue. Springs have their origin in the water which falls upon the earth, and sinks through porous soils till it arrives at a stratum impervious to water, where it forms subterranean reservoirs at various depths. When confined in this manner it is subject to the pressure of the water which fills the channels through which it has descended, and when this pressure is sufficient to overcome the resistance of the superincumbent mass of earth the water breaks through the superficial strata, and gushes forth in a spring. In descending downwards and rising upwards through various mineral masses the water of springs becomes impregnated with gaseous, saline, earthy, or metallic admixtures, as carbonic acid gas, sulphuretted hydrogen gas, nitrogen, carbonate of lime, silica, carbonate of iron, &c. When these substances are present in considerable quantity the springs become what are known as *mineral springs*, acquiring the peculiar properties which give them their medicinal value. Warm and hot springs are common, especially in volcanic countries, where they are sometimes distinguished by violent ebullitions. (See *GETSEYER*.) As a general rule springs are permanent in proportion to the depth to which the water which supplies them has descended from the surface. Some springs run for a time and then stop altogether, and after a time run again, and again stop; these are called *intermittent springs*. (See under *INTERMITTENT*.) Others do not cease to flow, but only discharge a much smaller quantity of water for a certain time, and then give out a greater quantity; these are called *variable* or *reciprocating springs*.

Stars are distinguished from planets by remaining apparently immovable with respect to one another, and hence they were called *fixed stars*, although their fixity has been disproved in numerous cases, and is no longer believed in regard to any. The principal points which form the subjects of astronomical inquiries regarding the stars are their apparent and relative magnitudes, their distribution, their number, their distances, motions, and nature. In order to distinguish the stars one from another the ancients divided the heavens into different spaces called constellations, which they supposed to be occupied by the figures of animals and other objects, as a lion, a bear, a man, a lyre, &c. (See *CONSTELLATION*.) The stars are divided, according to their brightness, into stars of the first, second, third, &c., magnitudes; but no magnitude, in the proper sense of the word, has yet been observed in any star. All the stars beyond the sixth or seventh magnitude are called *telescopic stars*, as they cannot be seen without the aid of the telescope. The gradations of magnitude among the telescopic stars are continued by astronomers from the eighth down to the sixteenth. The stars are very irregularly distributed over the celestial sphere. In some regions scarcely a star is to be seen, while in others they seem crowded together, especially in the Milky Way, where they appear, when viewed through a powerful telescope, to be crowded almost beyond imagination. Of the stars visible to the naked eye at any one time the number probably does not exceed a few thousands, but in the telescope their number is so great as to defy all calculation; and, besides, there is every reason to believe that there are countless hosts which lie beyond the reach of the most powerful telescopes. The distances of the fixed stars from the earth are very great. The nearest yet found, that of α Centauri, a double star in the southern hemisphere, being calculated at 20 billions of miles, so that light takes 3½ years to travel from it to our earth. Many stars have been observed whose light appears to undergo a regular periodic increase and diminution of brightness, amounting, in some instances, to a complete extinction and revival. These are called *variable* and *periodic stars*. It is found that some stars, formerly distinguished by their splendour, have entirely disappeared, others have shone forth with extraordinary brilliancy, and, after a longer or shorter period, have gradually died away and become extinct. These are called *temporary stars*. Many of the stars are found, when observed with telescopes of high magnifying power, to be composed of two, and some of them of three or more stars in close juxtaposition. These are termed *double* and *multiple stars*. The appearances known as nebulae are, in many cases at least, agglomerations of stars, separated from our system and from one another by unfathomable starless intervals. See *NEBULA*.—*Binary stars*, sidereal systems composed of two stars revolving about each other in regular orbits.—*Falling or shooting stars*. See **STARKE**.] (C₆H₁₀O₅ or C₁₂H₂₀O₁₀). A proximate principle of plants, universally diffused in the vegetable kingdom, and of very great importance. It occurs in seeds, as in those of wheat and other cereal grains, and also in leguminous plants; in roots, as in the tubers of the potato; in the stem and pith of many plants, as in the sago plant; in some barks, as in that of cinnamon; and in pulpy fruits, such as the apple. Finally, it is contained in the expressed juice of most vegetables, such as the carrot, in a state of suspension, being

deposited on standing. The starch of commerce is chiefly extracted from wheat flour. When pure, it is a snow-white powder of a glistening appearance,

which makes a crackling noise when pressed with the finger. It is composed of transparent rounded grains, the size of which varies in different plants, those of the potato being among the largest, and those of wheat and rice the smallest. It is insoluble in cold water, alcohol, and ether; but when heated with water it is converted into a kind of solution, which, on cooling, forms a stiff semi-opaque jelly. If dried up, this yields a translucent mass, which softens and swells into a jelly with water. It is employed for stiffening linen and other cloth. When roasted at a moderate heat in an oven it is converted into a species of gum employed by calico-printers; potato starch answers best for this purpose. (See **DEXTRINE**.) Starch is convertible into sugar by dilute sulphuric acid. Starch forms the greatest portion of all farinaceous substances, particularly of wheat flour, and it is the chief ingredient of bread. The woodcut shows the cells of the common potato (*Solanum tuberosum*) filled with starch granules, *a. a.*—2. A stiff formal manner; starchedness; as, to take the *starch* out of a person.

It consisted originally of a committee of the privy-council, and was remodelled during the reign of Henry VII., when it consisted of four high officers of state, with power to add to their number a bishop and temporal lord of the council, and two justices of the courts of Westminster. It had jurisdiction of forgery, perjury, riots, maintenance, fraud, libel, and conspiracy, and in general of every misdemeanour, especially those of public importance; it was exempt from the intervention of a jury, and could inflict any punishment short of death. Under Charles I. the scope of the Star-chamber was extended to cases properly belonging to the courts of common law, solely for the purpose of levying fines. Its process was summary, and often iniquitous, and the punishment it inflicted often arbitrary and cruel. This court was abolished by statute 16 Charles I.

It is covered with a tough leathery skin beset with prickles, and has the form of a star, with five or more rays radiating from a central disc. In the middle of the under surface of the disc is situated the mouth, opening into a digestive system which sends prolongations into each ray. If the prickly skin be removed it will be seen to be supported by a series of plates beautifully jointed together. On the under surface of each ray the plates exhibit a series of perforations, through which, in the living state, the ambulacra or tubular feet can be protruded so as to effect locomotion. Starfishes are found in almost all tropical and European seas, and some species are found as far north as Greenland. The cut shows two common British species, the one belonging to the five-rayed stars, the other to the sun-stars, with many rays. The latter has the rays twelve to fifteen in number.

Statice latifolia.

slightly connate; the stamens attached to
 the base of the petals; and the out ones
 seeded, inclosed in the calyx. Several spe-
 cies are natives of Britain, growing near the
 sea, most of them on muddy shores and in
 salt marshes. A number are cultivated in

statikē, the science which ascertains the

 of the properties and relations of forces in
 equilibrium—equilibrium meaning that the
 forces are in perfect balance, so that the body
 upon which they act is in a state of rest.
 According to the classification still employed
 by many writers on the subject the word
statics is used in opposition to *dynamics*,
 the former being the science of equilibrium
 or rest, and the latter of motion, both to-
 gether constituting *mechanics*. But among
 more recent authors *mechanics* is used to
 express not the theory of force and motion,
 but rather its application to the arts. The
 word *dynamics* is employed as expressing
 the science which treats of the laws of force
 or power, thus corresponding closely to the
 old use of the term *mechanics*; and this
 science is divided into *statics* and *kinetics*,
 the first being the science which treats of
 forces considered as producing rest, and the
 second as treating of forces considered as
 producing motion. The two great propo-
 sitions in statics are that of the lever and
 that of the composition of forces; but it
 also comprehends all the doctrines of the
 excitement and propagation of forces or
 pressures through the parts of solid bodies
 by which the energies of machines are pro-
 duced.—*Social statics*, that branch of so-
 ciology which treats of the forces which con-
 stitute or regulate society as it exists for

Steam (stēm), *n.* [A. Sax. *stēm*, *stēdm*, steam, vapour, smoke; D. *stoom*, Fris. *stoame*, steam; L.G. *stūm*, drift of snow or rain. Perhaps from a root *stam*, signifying dark, seen without the s in Skr. *tamas*, darkness, *timira*, dark.] 1. The vaporous substance into which water is converted under certain circumstances of heat and pressure; water in a gaseous state. Water gives off vapour or steam at every temperature — a low temperature not preventing the formation of steam, but only decreasing its density. The term, however, is strictly applied to the elastic aeriform fluid generated by heating water to the boiling-point. When water in an open vessel is heated to the temperature of 212° F., or to the boiling-point, globules of steam are formed at the bottom, and rise to the surface; and the continued application of heat, even though increased indefinitely, will only cause a more copious and rapid formation of steam, and will finally evaporate the whole of the water without raising the temperature of either. In this case all the heat which enters into the water is solely employed in converting it into steam of the temperature of boiling water. But if the water be confined in a strong close vessel, both it and the steam which it produces may be brought to any

temperature; and as steam at 212° occupies nearly 1700 times the space of the water from which it is generated, it follows that, when thus confined, it must exercise an enormous elastic or expansive force, which may also be shown to be proportional to its temperature. Steam which has received additional heat apart from water is called *superheated steam*, and approximates to the condition of a perfect gas. Steam, however, as used in the steam-engine holds water in suspension mechanically, and differs sensibly from the condition of a perfect gas. It is called *saturated or wet steam*. When the temperature of saturated steam is considerably above 212° F. the steam formed under such circumstances is termed *high-pressure steam*; at 212° F. it is termed *low-pressure steam*, and its pressure is equal to that of one atmosphere, or 14·7 lbs. on the square inch. Steam in its perfect state is transparent, colourless, and invisible; but when it has been deprived of part of its heat by coming into contact with cold air, it suddenly assumes a cloudy appearance, and is condensed into water. Hence appears another important property of steam, its condensibility; so that whenever cold is applied to it it suddenly returns to the liquid state, and thus can be employed to produce a vacuum. From the properties above briefly adverted to, steam constitutes an invaluable agent for the production of mechanical force, as exemplified in the vast and multiplied uses of the steam-engine. Steam is also employed as an agent in distributing the heat used for warming buildings, in heating baths, evaporating solutions, distilling, brewing, drying, dyeing, and even for cooking.—2. In *popular usage*, the visible moist vapour which rises from water, and from all moist and liquid bodies, when subjected to the action of heat; as, the *steam* of boiling water, of malt, of a tubed, &c. improvements from the hands of Newcomen, Beighton, Blakey, and others. Still, however, it was imperfect and rude in its construction, and was chiefly applied to the draining of mines or the raising of water. Up to this time it was properly an atmospheric engine, as the actual moving power was the pressure of the atmosphere, the steam only producing a vacuum under the piston. The steam-engine was brought to a high state of perfection by the celebrated James Watt about the year 1782. The numerous and vital improvements introduced by him, both in the combination of its mechanism and in the economy of its management, have rendered the steam-engine at once the most powerful, the most easily applied and regulated, and generally speaking the least expensive of all prime movers for impelling machinery of every description.

Steam-engine (stēm'en-jin), *n.* An engine worked by steam, or an engine in which the mechanical force arising from the elasticity and expansive action of steam, or from its property of rapid condensation, or from the combination of these principles, is made available as a source of motive power in the arts and manufactures, and in locomotion. The invention of the steam-engine has been ascribed by the English to the Marquis of Worcester, who published an account of it about the middle of the seventeenth century. By the French the invention has been ascribed to Papin towards the close of the same century. Papin's plan contained the earliest suggestion of a vacuum under a piston by the agency of steam. The first actual working steam-engine of which there is any record was invented and constructed by Captain Savery, an Englishman, to whom a patent was granted for it in 1698. This engine was employed to raise water by the expansion and condensation of steam. The steam-engine received great im-

provements very much in magnitude, form, and proportions, as well as in the details of the machinery by which the power of the steam is applied, but all work upon substantially the same principles which were embodied in Watt's steam-engine, and to understand one is to understand all. The above illustration represents a sectional elevation of a *Condensing Steam-engine*. The construction and action of the steam-engine will be readily understood from this illustration. The pipe which conveys the steam from the boiler opens into the part marked *l*, which incloses a movable valve by means of which the steam may be alternately admitted into the cylinder *a* by the upper port *c* and lower *d*; between these points the piston *b* works steam-tight. The valve *l* is so contrived that while it allows steam to pass into the cylinder through one of the ports, it shall at the same time open a communication between the opposite side of the piston and the condenser *c*, which is a hollow vessel kept constantly immersed in cold water, a portion of which is admitted into it by the injection-cock *o*; consequently, the steam thus admitted is instantly deprived of its heat, and reconverted into its original form of water, thereby forming a vacuum. Thus it will be seen that, on the communication being opened up between the boiler and either side of the piston, the latter will ascend or descend in the cylinder unimpeded by the resistance of the atmosphere against the other side, and with a force proportional to the pressure of the steam; and as the motions of the steam-valve *l* are regulated by the engine itself, the above action is kept up continuously. The alternating rectilinear motion thus generated within the cylinder is transmit-

ted, by means of a rod attached to the piston, to a strong beam *ff*, movable upon a central axis, a system of jointed rods *ee*, called the *parallel motion*, being interposed for the purpose of neutralizing the disturbing action which the circular path of the beam would otherwise exert upon the piston. The reciprocating motion of the beam is now, through the intervention of the connecting-rod *g* and crank *h*, converted into a circular or rotatory motion, which is rendered continuous and uniform by the fly-wheel *i*, to the axis of which the machinery to be impelled is connected. The air-pump *p* for withdrawing the vapour and water from the condenser, the feed-pump *s* for supplying the boilers, and cold-water pump *t* for supplying the condenser cistern, are all worked by rods from the beam; and the governor *u*, for maintaining uniformity of motion, is driven by a band from the crank-shaft. The above description refers more immediately to that class of steam-engines called *low-pressure* or *condensing* engines, in which the power derived from the rapid condensation of the steam is made available in combination with that due to its elasticity; but if we suppose the condensing apparatus removed, and the waste steam allowed to escape into the atmosphere, it will then be equally applicable to that kind called *high-pressure* or *non-condensing* engines, which employ the elastic action of the steam alone. Steam-engines are classified in various ways, as *portable*, *marine*, *locomotive*, *pumping*, *blowing*, *winding*, &c. According to the arrangement of the chief parts they are classed as *beam*, *oscillating-cylinder*, *horizontal*, *vertical*, &c. The mechanical energy of a steam-engine is usually estimated in horse-power. See HORSE-POWER.

Steam-gauge (stēm'gāj), *n.* An attachment to a boiler to indicate the pressure of steam; a pressure-gauge. There are many forms. One of the older is a bent tube partially filled with mercury, one end of which springs from the boiler, so that the steam raises the mercury according to the amount of pressure. A very common form of gauge is that known as Bourdon's, which consists essentially of a flattened metal tube, closed at one end and bent circularly, into which the steam is admitted. As such a tube tends to straighten itself out by the force of the steam the amount of pressure can easily be ascertained by an attached index apparatus.

Steam-gun (stēm'gun), *n.* A gun the projectile force of which is derived from the expansion of steam issuing through a shotted tube.

Steam-hammer (stēm'ham-ēr), *n.* A form of heavy force hammer operated by steam, consisting usually of a steam cylinder and piston, with metal striker attached, placed vertically over the anvil. There are two principal varieties: In one the cylinder is fixed, and the hammer is attached to the piston-rod, and is operated by the direct action of the steam in the cylinder; in the other the piston is fixed, and the hammer is attached to the lower end of the cylinder, which similarly rises and falls by the action of the steam in the cylinder. The former is known as Nasmyth's, and the latter as Condie's hammer, which is shown in the cut attached. In the tabular figure is a steam and exhaust valve, and attached to it a hollow piston-rod, acting as steam and exhaust pipe, to which the piston is attached as a fixture. The steam, being introduced into the cylinder or hammer immediately above the piston, presses the cylinder cover,

and raises the hammer between the guides to the required height. The steam being then cut off, and the exhaust-valve opened,

Steam-hammer.

the hammer falls, not only with the velocity of gravity, but with the additional velocity produced by the compression of the air under the piston during the latter portion of the hammer's ascent, which, acting as a recoil, adds considerably to the effect of the blow. With the most powerful hammers steam is also introduced on the under side of the piston, so as to augment still further the speed and force of the blow. The valves and valve-gearing are so arranged that the person in charge of the machine can arrest the motion of the hammer while falling, or cause it to fall at any moment while ascending. In Ramshotton's hammer two hammer cylinders move horizontally in the same line, but in opposite directions, and the piece to be forged is placed between the two. There are some other kinds of steam-hammers suitable for light work, in most of which the hammer-head is attached to the end of a horizontal shaft which acts as a lever, the fulcrum of which is nearer the free end of the shaft than the end bearing the hammer. The hammer is raised by cams attached to a revolving drum, and falls when by the revolution of the drum the shaft is freed from one of the cams. These are often called *Steam-tits*.

Another thin brass cup *d* is fixed in an inverted position at a short distance above the upper surface of the parts *b* and *c*, so as to present a sharp edge exactly opposite the orifice above mentioned. great violence through the circular orifice, encounters the edge of the cup *c*, and thereby produces a loud and shrill sound which may be heard at the distance of several miles. Stearic (stē'a-rik), *a.* Of, pertaining to, or obtained from stearine.—*Stearic acid* ($C_{18}H_{36}O_2$), a monobasic acid, perhaps the most important and most abundant of the fatty acids. It exists in combination with glycerine, as stearine, in beef and mutton fat, and in several vegetable fats, such as the butter of cacao. It is obtained from stearine by saponification, and also from mutton suet by a similar process. Stearic acid is in the form of brilliant white scaly crystals; it is inodorous, tasteless, insoluble in water, but soluble in alcohol and ether. It burns like wax, and is used in the formation of candles. It forms compounds with the alkalies, earths, and metallic oxides, which are called stearates.

Stearine, Stearin (stē'a-rin), *n.* [*Gr. stear*, suet.] ($C_{18}H_{36}O_2$). 1. The chief ingredient of suet and tallow, or the harder ingredient of animal fats, oleine being the softer one. It is obtained from mutton suet by repeated solution in ether and crystallization. It may also be obtained by pressing tallow between hot plates, and afterwards dissolving in hot ether, which on cooling deposits the stearine. It has a pearly lustre, is soft to the touch, but not greasy. It is insoluble in water, but soluble in hot alcohol and ether. When treated with superheated steam it is separated into stearic acid and glycerine, and when boiled with alkalies is saponified, that is, the stearic acid combines with the alkali, forming soap, and glycerine is separated. When melted it resembles

wax. There are three stearines, which may be all regarded as derivatives of glycerine in which one, two, or three O.H. groups are replaced by the radical stearyl. Natural stearine is the tristearyl derivative of glycerine.—2. A popular name for stearic acid as used in making candles.

Wachter and Adelung connect the word with G. *stahel*, a prick, from *stechen*, to stick, to prick, on type of Fr. *acier*, steel, from L. *acies*, a point, an edge.] 1. Iron combined with a small portion of carbon. Steel usually contains also small quantities of silicon, phosphorus, manganese, and sulphur, but iron and carbon appear to be its only essential constituents. The relative proportions of iron and carbon vary in steel of different qualities; but in that used for ordinary purposes the carbon amounts from about 0.5 to 1.5 per cent, the toughness, tenacity, and hardness increasing with the increase of the carbon, the elasticity diminishing as the hardness increases, and *vice versa*. At a red heat steel is malleable and may be welded. The colour is a bright grayish white, the texture closely granular, the specific gravity varying from 7.62 to 7.81. Steel formed from bar-iron by cementation is called *blistered steel*, from its surface ac-

quiring a *blistered* character in the process. (See CEMENTATION.) When blistered steel is rolled or beaten down into bars, it is called *shear-steel*, and if it is melted, cast into ingots, and again rolled out into bars, it forms *cast-steel*. Cast-steel is now largely manufactured by what is known as Bessemer's process. (See BESSEMER'S PROCESS.) Natural or German steel is an impure and variable kind of steel procured from cast-iron, or obtained at once from the ore. The natural steel yielded by cast-iron, manufactured in the refining houses, is known by the general name of *furnace steel*, and that which has only been once treated with a refining furnace is particularly called *rough steel*. The peculiarity of steel, upon which its high value in the arts in a great measure depends, is its property of becoming hard after being heated to redness and then suddenly cooled by being plunged into cold water, and of being again softened down to any requisite degree by the application of a certain temperature. This process is called *tempering*. It is found that the higher the temperature to which steel is raised, and the more sudden the cooling, the greater is the hardness; and hence, any degree of hardness can be given to steel which is required for the various purposes to which it is applied. According to the degree of hardness to which steel is tempered it assumes various colours, and formerly these colours served as guides to the workman. Now, however, a thermometer, with a bath of mercury or oil, is employed, and the operation of tempering is performed with a much greater degree of certainty. The uses of steel in forming various kinds of instruments, edge-tools, springs, &c., are well known.—*Indian steel*. See WOOL.—2. *Fig.* a weapon; particularly, an offensive weapon, as a sword, spear, and the like.

-Ster. A termination as in *maistler*, *gamester*, *spinster*, *songster*, denoting occupation. In the earliest times, and up to about the end of the thirteenth century, it was generally the sign of the feminine gender, corresponding to the masculine *-ete* or *-er*. In the fourteenth century it began to give place as a feminine termination to the Norman *-ess*. In modern literary English there is now only one feminine word with this affix, viz. *spinster*, but *huckster* was used very late as a feminine; and in Scotch and provincial English *sewster* is still used. When the affix *-ster* was felt no longer to mark the feminine distinctively, some new feminines were formed by the addition of the termination *-ess* to the *-ster*, as *songstress* and *seamstress*.

The suffix *-ster* now often marks the agent with more or less a sense of contempt and depreciation, as *punster*, *trickster*, *gamester*. Dr. Morris.

But we cannot recognize the termination *-ster* as being, or as having been at some time past, a feminine formative in every instance. Not only does the present use of such old words as *Baxter*, *huckster*, *maistler*, *songster*, *Webster*, not to urge the more recent *oldest*, *youngster*, *roadster*, make it hard to prove them all feminines; but even if we push our inquiries further back we nowhere find the group clearly defined as such except in modern Dutch. There was in Anglo-Saxon *bacere* and *bacestre*, and yet Pharaoh's brother in Genesis xi. is *hazester*. Grimm conjectured that these nouns in *-estre* are all that is left of an older pair of declensions, whereof one was masculine in *-estra*, the other feminine in *-estre*. J. Earle.

Stereoscope (stér-è-ò-skóp), *n.* [Gr. *stereos*, solid, and *skopeō*, to view.] An optical instrument to illustrate the phenomena of binocular vision. An object viewed by both eyes does not appear to each under the same angle; hence whatever we look upon is apprehended by the sense of vision through the medium of two distinct images which unite in the sensorium of the brain and give us the idea of substance and solidity. The stereoscope is an optical apparatus which enables us to look upon two pictures taken under a small difference of angular view, each eye looking upon one picture only; and thus, as in ordinary vision, two images are conveyed to the brain which unite into one, exhibiting the objects represented under a high degree of relief. A reflecting form of stereoscope was invented

Stereoscope.

by Sir C. Wheatstone in 1838. It is so constructed that the two pictures are reflected to the eyes from two small plane mirrors placed at right angles the faces being towards the observer. Subsequently Sir D. Brewster invented the lenticular or refracting stereoscope, based on the refractive properties of

semi-double convex lenses. This is the one now in general use. There are many forms of it, one of which is shown in the figure. *a a* are tubes containing the two halves of a lens; *b b* is a glass slide on which the two views are depicted by the photographic process; *c* is a flap, covered with a light-coloured paper to receive the light and reflect it upon the slide, the lid on the top admitting light when the pictures are opaque. When the tubes *a a* are adjusted to suit the eye the observer takes the one picture into the right eye and the other into the left eye, but the perceptive faculty apprehends only one image, and that in bold substantial relief and intensity.

Stereotrope (stér-è-ò-tróp), *n.* [Gr. *stereos*, solid, and *trōpe*, a turning, from *trēpō*, to turn.] An instrument by which an object is perceived as if in motion and with an appearance of solidity or relief as in nature. It consists of a series of stereoscopic pictures, generally eight, of an object in the successive positions it assumes in completing any motion, affixed to an octagonal drum revolving under an ordinary lenticular stereoscope, and viewed through a solid cylinder pierced in its entire length by two apertures, which makes four revolutions for one of the picture-drum. The observer thus sees the object constantly in one place, but its parts apparently in motion and in solid and natural relief.

Stereotype (stér-è-ò-tip), *n.* [Gr. *stereos*, fixed, and *typos*, type, form.] 1. *Lit.* fixed metal type; hence, a plate cast from a stucco or papier-mâché mould, on which is a facsimile of the superficies of arranged types, which plate being fitted to a block may be used under the press exactly as movable types are used, and being retained may serve at any time to throw off an additional impression. The plates are composed of an alloy similar to ordinary type-metal. The original process, invented by Mr. William Ged, a goldsmith of Edinburgh, consisted in taking a stuccocast of a form of type, which, after being subjected to a gradual baking, was used as a mould to obtain the facsimile of the form of type. This process has been greatly supplanted by what is known as the papier-mâché process. This generally consists in covering the form, the face of which is oiled, with a soft, moist matrix of several sheets of tissue, blotting, and brown paper, stuck together by a mixture of glue, paste, and powdered French chalk, the tissue paper being next the type. A wet linen cloth is laid over the paper, and the matrix is dabbed by a beating-brush so as to drive the soft paper into all the interstices between the letters of the form. The hollows which now appear in the back are filled up by a smooth coat of stucco; and the matrix, after being backed up by a sheet of strong paper, is next subjected to a heavy pressure over a steam-chest and thoroughly dried while still connected with the type. It is then removed and placed in a casting-box, into which molten metal is poured, so as to produce from the matrix a plate with the type in relief. When the metal is set the mould is opened, the matrix removed, and the plate trimmed and prepared for use. For rotary printing-machines both matrix and plate form the segment of a circle to enable the plate to fit on to the impression cylinder. For printing the finer class of illustrated books, &c., plates are produced by the process of electrotyping. See ELECTROTYPE. — *Stereotype block*, a block of wood on which a stereotype is mounted to make it type high. 2. Stoic (stó'ik), *n.* [Gr. *Stoikos*, from *Stoa*, a porch in Athens where the philosopher Zeno taught.] 1. A disciple of the philosopher Zeno, who founded a sect about 308 B.C. He taught that men should be free from passion, unmoved by joy or grief, and submit without complaint to the unavoidable necessity by which all things are governed. The Stoics are proverbially known for the sternness and austerity of their ethical doctrines, and for the influence which their tenets exercised over some of the noblest spirits of antiquity, especially among the Romans. Their system appears to have been an attempt to reconcile a theological pantheism and a materialist psychology with a logic which seeks the foundations of knowledge in the representations or perceptions of the senses, and a morality which claims as its first principle the absolute freedom of the human will. The Stoics teach that whatever is real is material; matter and force are the two ultimate principles; matter is of itself motionless and unformed, though capable of receiving all motions and all forms. Force is the active, moving, and moulding principle, and is inseparably joined with matter; the working force in the universe is God, whose existence as a wise thinking being is proved by the beauty and adaptation of the world. The supreme end of life, or the highest good, is virtue, that is, a life conformed to nature, the agreement of human conduct with the all-controlling law of nature, or of the human with the divine will; not contemplation, but action, is the supreme problem for man; virtue is sufficient for happiness, but happiness or pleasure should never be made the end of human endeavour. The wise man alone attains to the complete performance of his duty; he is without passion, although not without feeling; he is not indulgent, but just toward himself and others; he alone is free; he is king and lord, and is inferior in inner worth to no other rational being, not even to Zens himself. Stomach (stum'ak), *n.* [L. *stomachus*, the gullet, œsophagus, stomach, from Gr. *stomachos*, the throat, the gullet, from *stoma*, a mouth.] 1. A membranous receptacle, the principal organ of digestion, in which food is prepared for nourishing the body. The human stomach is of an irregularly conical or pear-shaped form; it is situated in the epigastric region, lying almost transversely across the upper and left portion of the abdominal cavity. Its largest extremity is directed to the left, its smaller to the right. Its superior orifice, where the œsophagus terminates, is called the *cardia*; the inferior orifice, where the intestine begins, the *pylorus*. The stomach is composed of three coats or membranes, connected by a firm but very extensive cellular tissue. The external or peritoneal coat is a dense firm membrane; the internal or mucous coat is soft and vascular; the central coat is muscular. The glands of the stomach are situated in the mucous coat. The arteries of the stomach come chiefly from the celiac artery, and are accompanied by veins which terminate in the *vena porta*, or veins conveying venous blood to the liver for the purpose of secreting bile. The nerves of the stomach are very numerous, and come from the eighth pair and the sympathetic nerve. The lymphatic vessels are distri-

buted throughout the whole substance, and proceed immediately to the thoracic duct. The stomach owes its digestive powers chiefly to the gastric juice, an acid liquid which is secreted by innumerable follicles in the mucous coat, and the action of which upon various elements of food is somewhat similar to that of prolonged boiling in water. Digestion is also aided by the performance of certain well-defined stomachic movements, which are well calculated to mix and thoroughly combine the food particles with its contained fluids. In mammals there are three kinds of stomachs, *simple*, *complex*, and *compound*. In the *simple* it consists of a single cavity, as in man and the Carnivora, &c. This is the most common form. The *complex* has two or more compartments communicating with each other, with no marked difference of structure, as in the kangaroo, squirrel, porcupine, &c. The Cetacea have from five to seven such compartments. The *compound* stomach is peculiar to the ruminants. It consists of four compartments, differing materially in size and in the structure of the lining mucous membrane. The first and largest cavity is the *paunch* or *rumen*, into which the food is first received; the second, the *honeycomb* or *reticulum*, so named from its lining membrane forming deep polygonal cells; the third, the *paalterium* or *omasum*, called 'manyplies' or 'monipplies' (Scottish), from its foliated structure. All these three compartments are merely useful in the preparing the food for the fourth or true stomach, called also *reed* or *abomasum*, where the gastric juice is secreted and food finally digested. See RUMINATION.—2. Any specialized cavity for the digestion of food, such as the digestive cavity in Hydrozoa, &c.—3. When the object is to extract from the stomach, the pump is worked while its sucking orifice is in connection with a flexible tube passed into the stomach; and the extracted matter escapes by the forcing orifice. The deposition of successive layers of sand and gravel in the bed of a river, or in a canal, affords an illustration both of the form and origin of strata. Geologists generally make a distinction between a *stratum* and a *bed*, restricting the latter term to the thicker kind of strata; others, however, use the terms synonymously. Strata may be said to vary in thickness from a few inches to several feet. A single stratum again is often seen to be made up of thinner layers, called *laminae*. Strata are separated from each other by seams or parallel planes, and sometimes by joints or fissures, forming some angle with the planes. When strata do not lie horizontally but are inclined, they are said to *dip* towards some point of the compass, and the angle they make with the horizon is called the *angle of dip* or *inclination*. The direction or *strike* of the strata is indicated by a horizontal line at right angles to the dip. When strata protrude above the surface, or appear uncovered, they are said to *crop out*. They are said to be *conformable* when their planes are parallel, whatever their dip may be; and *unconformable* when a set of them are connected with another, so that the planes of stratification of the one series have a different direction from that of the other series. On examining the crust of the earth we find that it consists chiefly of distinct strata of different materials. These differ in depth and extent, but they are found to follow each other on the large scale, as masses in an apparently regular and uniform succession, in all places, districts, and countries, where they admit of examination, and have been attentively studied. They appear in most instances to rest upon, and are blended with, inviolated, and in some few instances, overflowed, as it were, by unstratified rocks. See *GEOLOGY*.—2. A bed or layer artificially made of some material.

It is remarkable for the manner in which the receptacle, commonly called the fruit, increases and becomes succulent; the proper fruit being the small achenia which it bears upon its surface. The species are perennial plants, throwing out runners; the leaves are trifoliate, each leaflet being coarsely toothed. The receptacle is round, and assumes a variety of colours, from a scarcely perceptible pink to a dark red. All the species are natives of temperate or cold climates, and are found in Europe, America, and the mountains of Asia. The following species afford the varieties of cultivated strawberries: (1) *Wood strawberry* (*F. vesca*), found wild in woods and on hillsides throughout Europe, and abundant in Great Britain. Strength (strength), *n.* [A. Sax. *strength*, strength, from *strong*, strong; comp. *length* and *long*. See **STRONG**.] 1. That property, attribute, or quality of an animal body by which it is enabled to move itself or other bodies. The strength of animals is the muscular force or energy which they are capable of exerting; as, not to have *strength* enough to lift the arm or to walk. In order to compare the effects produced by different animals, or the same animal under different circumstances, it is usual to estimate the force required to raise or transport 1 lb. through 1 foot of space in 1 minute of time, which force is called the *dynamic unit*. Hence, if an animal, as a horse, for example, is capable of raising 33,000 lbs. 1 foot high in a minute, he must exert a force 33,000 times greater than that required to raise 1 lb. through the same space in the same time. Of the different modes of estimating human strength the most practically useful is the observation of the average effect produced daily by a labourer who continues his exertions for a number of successive days, as in transporting materials in a wheel-barrow, carrying or dragging a load, working a pump, turning a wind, rowing a boat, &c.—2. The quality of bodies by which they sustain the application of force without breaking or yielding; solidity or toughness; as, the *strength* of a bone; the *strength* of a beam; the *strength* of a wall; the *strength* of a rope. The conditions which determine the strength of solid bodies, and their power to resist forces tending to produce fracture, are found by experiment. A force acting on solid bodies may tend to separate its parts in different ways. Thus a body may be torn asunder by a stretching or tensile force or direct pull applied in the direction of its fibres, as in the case of ropes, &c.; or it may be broken across by a transverse strain, crushed by a pressure exerted in the direction of its length, twisted, shorn across, &c.—3. Power or vigour of any kind; ability to do or bear; capacity for exertion, whether physical, intellectual, or moral; as, *strength* of mind, memory, or judgment; *strength* of evidence, argument, or persuasion; *strength* of feeling, affection, and the like.

That quality which tends to secure results; the effective power in an institution or what is established; legal or moral force; the quality of binding, influencing, or constraining; as, the *strength* of social or legal obligations; the *strength* of law; the *strength* of public opinion or custom.—10. Strontia (stron'shi-a), *n.* (SrO.) An oxide of strontium occurring in a crystalline state, as a carbonate, in the lead-mines of *Strontian*, in Argyleshire, whence its name. It was discovered by Dr. Hope in 1792. It has subsequently been found in England, America, and France; but strontite minerals are rather rare. The pure earth to which the name of strontia is given is prepared from the carbonate exactly like baryta. It is a grayish-white powder, infusible in the furnace; of a specific gravity approaching that of baryta, having an acrid burning taste, but not so corrosive as baryta, though sharper than lime, and an alkaline reaction. It becomes hot when moistened, and slakes into a pulverulent hydrate (Sr(OH)₂), dissolves in 150 parts of water at 60°, and in much less at the boiling-point, forming an alkaline solution called *strontia water*, which deposits crystals in four-sided tables as it cools. These crystals have the composition Sr(HO)₂.SiH₂O. It is readily distinguished from baryta by forming with hydrochloric acid a chloride which crystallizes in needles, and is very deliquescent, and soluble in alcohol, to which it gives the property of burning with a crimson flame. The sulphate of strontia is found native, and some of the native varieties have a pale blue tint, whence the term *celadon* (which see). The nitrate of strontia is used in making fireworks, as it communicates a magnificent red colour to flame.

It is a dark yellow substance, less lustrous than barium; sp. gr. 2.54; it is difficultly fusible, and not volatile. When exposed to the air it attracts oxygen, and becomes converted into strontia, or protoxide of strontium; when thrown into water it decomposes it with great violence, producing hydrogen gas, and forming with the water a solution of strontia. Strontium is harmless, while barium and all its compounds are poisonous.

A ganoid fish of the genus *Acipenser*, family Sturionidae, the members of which family are popularly included under the name sturgeon. The general form of the sturgeon is similar to that of the shark, but the body is covered with numerous bony plates in longitudinal rows; the exterior portion of the head is also well mailed; the mouth placed under the snout is small and edentate; the palatal bones, soldered to the maxillaries, convert them into the upper jaw. The mouth, placed on a pedicel that has three articulations, is more protractile than that of a shark. The eyes and nostrils are on the side of the head, and cirri are inserted under the snout. On the back is a single dorsal fin, and the tail is forked. The sturgeons ascend the larger rivers of Europe in great abundance, and are the objects of important fisheries. The flesh of most of the species is wholesome and agreeable food; their roe is converted into caviare, and their air-bladder affords the finest isinglass. The common sturgeon (*Acipenser sturio*) is found in most of the large rivers of Europe. Its flesh is delicate and well-flavoured, somewhat resembling veal. When caught in the Thames, within the jurisdiction of the Lord-mayor of London, it is a royal fish, reserved for the sovereign. The sterlet (*A. ruthenus*) is found in the Volga and the Danube. (See STERLET.) The great or white sturgeon, or beluga (*A. huso*), is found in the Danube, the Volga, and other rivers running into the Black and Caspian Seas. It frequently exceeds 12 and 15 feet in length, and weighs

above 1200 pounds. The flesh is not much esteemed, but the finest isinglass is made from its air-bladder. There are several species peculiar to North America.

The style which deals in long sentences or in short sentences, or indeed which has any trick in it, is a bad style. . . . The best thing which, to my mind, has been ever said about style was said in a metaphorical way, the writer declaring that the style should, as it were, involve and display the subject-matter, as the drapery in a consummate statue folds over and around the figure. *Sir A. Helps.*

4. Mode of presentation, especially in music or any of the fine arts; characteristic or peculiar mode of developing an idea or accomplishing a result. Style in the arts depends on the character of the artist, the subjects, the art itself, the materials used, the object aimed at, &c. The style varies in different periods, and is also influenced by differences of national character. The various branches of an art, too, have each its peculiar style. Thus in poetry there are the epic, lyric, and dramatic styles; in music, the sacred, opera, and concert styles, the vocal and instrumental styles, the sonata and symphony styles, &c.; in painting there are the historical, landscape, &c., styles.—5. External manner or fashion; often, manner deemed elegant and appropriate in social demeanour; fashion; as, the entertainment was got up in excellent style.—6. Phrase of address or appellation; formal or official designation; title; as, any one having the style of majesty 'One style to a gracious benefactor, another to a proud insulting foe.' *Burke*.—7. In arch., a particular character as to the gen-

eral artistic idea pervading a building; as, the Gothic style, the Grecian style, the Moorish style, the Norman style, &c.—8. In *chron.* a mode of reckoning time with regard to the Julian and Gregorian calendar. (See GREGORIAN, JULIAN.) Style is *Old* or *New*. The *Old Style* follows the Julian manner of computing the months and days, in which the year consists of 365 days and 6 hours. This is something more than 11 minutes too much, and in the course of time, between Cæsar and Pope Gregory XIII., this accumulated error amounted to 10 days. Gregory reformed the calendar by retrenching 10 days, and fixing the ordinary length of the civil year at 365 days; and to make up for the odd hours it was ordained that every fourth year (which we call *leap-year*) should consist of 366 days. But the true length of the solar year is only 365 days 5 hours 48 minutes 51.6 seconds; hence, four solar years would fall short of four years of 365 days 6 hours each, or of four Julian years, three of 365 days and one of 366 days, by 44 minutes 33.6 seconds, and 400 solar years would fall short of 400 Julian years by 74 hours 16 minutes, or by a little more than three days. This error it was ordained should be rectified by omitting three days in three of the four years which completed centuries; or, in other words, that the centuries divisible without remainder by 400, should alone of the centuries be accounted leap-years. Thus 1600, 2000, 2400 would be leap-years, but not 1700, 1800, 1900, 2100, 2200, 2300. This mode of correcting the calendar has been adopted at different times in almost all civilized nations with the exception of Russia and those countries where the Greek Church is predominant, which still adhere to the *Old Style*. In England the Gregorian or *New Style* was adopted by act of parliament in 1752, and as one of the years concluding a century in which the additional or intercalary day was to be omitted (the year 1700) had elapsed since the correction by Pope Gregory, it was necessary to omit 11 instead of 10 days in the current year. Accordingly 11 days in September, 1752, were retrenched, and the 3d day was reckoned the 14th. The difference between the *Old* and *New Styles* is now 12 days.—*Style of a court, in law*, the practice observed by any court in its way of proceeding.—*Juridical styles*, in *Scots law*, the particular forms of expression and arrangement necessary to be observed in formal deeds and instruments.—*Dictionary, Phraseology, Style*. See under DICTION.

Sublimate (sub'li-māt), *a.* Brought into a state of vapour by heat, and again condensed, as solid substances.

Sublimation (sub-li-mā'shon), *n.* 1. In chem. the act or process of sublimating; a process by which solid substances are, by the aid of heat, converted into vapour, which is again condensed into the solid state by the application of cold. Sublimation bears the same relation to a solid that distillation does to a liquid. Both processes purify the substances to which they are severally applied, by separating them from the fixed and grosser matters with which they are connected. Sublimation is usually conducted in one vessel, the product being deposited in the upper part of the vessel in a solid state, and often in the crystalline form, while the impurity remains in the lower part. If iodine, for example, be heated in a Florence flask a purple vapour rises, which almost immediately condenses in small brilliant, dark-coloured crystals in the upper part of the flask, the impurity remaining in the lower. The vapour of some substances which undergo the process of sublimation condenses in the form of a fine powder called *flowers*; such are the flowers of sulphur, flowers of benzoin, and others of the same kind. Other sublimates require to be in a solid and compact form, as camphor, hydrochlorate of ammonia, and all the sublimates of mercury.—2. Sublimity (sub-lim'iti), *n.* [Fr. *sublimité*; L. *sublimitas*, from *sublimis*, elevated. See **SUBLIME**.] 1. The state of being sublime; that character or quality of anything which marks it as sublime; grandeur; especially, (a) height in excellence; loftiness of nature or character; moral grandeur; as, God's incomprehensible *sublimity*; the *sublimity* of an action.

(c) Grandeur; vastness; elevation, whether exhibited in the works of nature or of art; as, the *sublimity* of a scene or of a building. 2. The emotion produced by what is sublime; a feeling produced by the contemplation of great scenes and objects, or of exalted excellence. *Note.* The true nature of sublimity, whether of the emotion or that which causes it, is a subject of great interest and importance in mental philosophy, and it has always been a favourite subject of speculation. The invariable condition of sublimity in objects, either material or moral, is vastness, power, or intensity. The invariable condition of the emotion of sublimity—that which distinguishes this emotion from every other emotion—is a comprehension of this vastness or power, with a simultaneous feeling of our own comparative insignificance. The antithesis to the emotion of sublimity is the emotion of contempt. In every case of sublimity in material objects, whatever feelings may simultaneously concur, vastness will be found to be an invariable condition—vastness either of form or of power, as in the violent dashing of a cataract, in the roar of the ocean, in the violence of the storm, in the majestic quiet of Mount Blanc, preserving its calm amidst all the storms that play around it. In the moral world the invariable condition of sublimity is intensity. More intensity is sufficient to produce the sublime. Lear, who appeals to the heavens, 'for they are old like him,' is sublime from the very intensity of his sufferings and his passions. Lady Macbeth is sublime from the intensity of her will, which crushes every female feeling for the attainment of her object. Scævola, with his hand in the burning coals, exhibits an intensity of will which is sublime. In all the cases above mentioned we are moved by a vivid feeling of some greater power than our own, or some will more capable of suffering, more vast in its strength, than our feeble vacillating will.—3.† The sublimest or highest degree of anything; the height.

The *sublimity* of wisdom is to do those things living, which are to be desired when dying.

6. In philos. that which underlies or is the permanent subject or cause of all phenomena, whether material or spiritual; the subject which we imagine to underlie the attributes or qualities by which alone we are conscious of existences; that which exists independently and unchangeably, in contradistinction to accident, which denotes any of the changeable phenomena in substance, whether these phenomena are necessary or casual, in which latter case they are called accidents in a narrower sense. The relation of accident to substance is called the relation of inherence, and corresponds to the logical relation of subject and predicate, because the substance is the subject to which are assigned the qualities, states, and relations as predicates; substance itself is the essence which is capable of these phenomena, and in spite of these changes remains the same. Substance is, with respect to the mind, a merely logical distinction from its attributes. We can never imagine it, but we are compelled to assume it. We cannot conceive substance shorn of its attributes, because those attributes are the sole staple of our conceptions; but we must assume that substance is some-

thing different from its attributes. Substance is the unknown, unknowable substratum on which rests all that we experience of the external world.—7. In *theol.* that which forms the divine essence or being; that in which the divine attributes inhere.

—*Sufficient reason*, according to the philosophical system of Leibnitz, a principle which admits nothing to exist without a sufficient reason of its existence, though that reason may not be known to us. Of contingent truths or facts, a sufficient reason must be found which may be traced up through a series of preceding contingencies till they ultimately terminate in a necessary substance, which is a sufficient reason of the whole series of changes, and with which the whole series is connected. In this way Leibnitz demonstrated the being of God. The same principle has been employed in mathematics to prove the equality of symmetrical solids or magnitudes which cannot be made to coincide or to fill the same space. Playfair, in his notes to his edition of Euclid's Elements, has expressed this principle as a general axiom, thus: 'Things of which the magnitude is determined by conditions that are exactly the same, are equal to one another; or two magnitudes A and B are equal, when there is no reason that A should exceed B, rather than that B should exceed A.' By the aid of the principle of *sufficient reason* we can compare geometrical quantities, whether they be of one, of two, or of three dimensions, nor is there any danger of being misled by this principle so long as it is confined to the objects of mathematical investigation; but in physical and metaphysical questions it cannot be applied with equal safety, because in such cases we have seldom a complete definition of the thing which we reason about, or one which includes all its properties.—**SYN.** Enough, adequate, competent, full, satisfactory, ample, abundant.

Sugar (shū-gēr), *n.* [Fr. *sucre*, It. *zucchero*, not from L. *saccharum*, Gr. *sakcharon*, sugar, but from the Ar. *sukkar*, sugar, which has also produced the Sp. and Pg. *azúcar*. Sugar was little known in Europe till the time of the crusades. The Greek and Arabic words are from Per. *shakhara*, Prakrit *sakkara*, Skr. *ṣarkara*, sugar. The Sanskrit form signified originally grains of sand, and was transferred to sugar which resembles such grains. The root is Skr. *cri*, to break into fragments.] 1. A well-known sweet granular substance, prepared chiefly from the expressed juice of the sugar-cane (*Saccharum officinarum*), but obtained also from a great variety of other plants, as maple, beet-root, birch, parsnip, &c. The process of manufacturing cane-sugar consists, generally, in pressing out the juice of the canes by passing them between the rollers of a rolling-mill. (See **SUGAR-MILL**.) The juice is received in a shallow trough placed beneath the rollers. This saccharine liquor is concentrated by boiling, which expels the water; lime is added to neutralize the acid that is usually present; the grosser impurities rise to the surface, and are separated in the form of scum. When duly concentrated the syrup is run off into shallow wooden coolers, where it concretes; it is then put into hogsheads with holes in the bottom, through which the molasses drain off into cisterns below, leaving the sugar in the state known in commerce by the name of *raw* or *muscovado* sugar. This is further

purified by solution in water and filtration, first through cotton bags, then through layers of animal charcoal, boiling down under diminished pressure, and crystallization. Thus clarified it takes the names of *lump, loaf, refined, &c.*, according to the different degrees of purification. The manufacture of sugar from beet-root is carried on to a very considerable extent in France, Germany, Austria, Belgium, Holland, Russia, &c. In the United States and in Canada great quantities of sugar are obtained from the sap of the sugar-maple (*Acer saccharinum*). Sugar is a proximate element of the vegetable kingdom, and is found in most ripe fruits and many farinaceous roots. By fermentation sugar is converted into alcohol, and hence forms the basis of those substances, as molasses, grapes, apples, malt, &c., which are used for making intoxicating liquors. The West Indies, Brazil, British Guiana, and Java are the principal sources whence our supplies of cane-sugar are derived; the sugar used on the Continent is chiefly obtained from the beet. Sugar was only vaguely known to the Greeks and Romans; it seems to have been introduced into Europe during the time of the crusades. The cane was grown about the middle of the twelfth century in Cyprus, whence, some time later, it was transplanted into Madeira, and about the beginning of the sixteenth century it was hence carried to the New World. Of all vegetable principles it is considered by many eminent physicians as the most wholesome and nutritious. Chemically, sugar is the representative of a class to which the name of *sucrose* or *saccharose* is given. Besides the sucroses the chemist is acquainted with another group of bodies represented by the sugar of most fruits, which he calls *glucoses*. The sucroses have the general formula $nC_{12}H_{22}O_{11}$; the glucoses, the general formula $nC_{6}H_{12}O_5$ (n being a whole number, whether unity or greater than unity is not as yet certainly known). When completely oxidized all sugars yield carbon dioxide and water; much heat is evolved during the oxidation.—2 That which resembles sugar in any of its properties; as, *sugar of lead*, the acetate of lead, called *saccharum saturni* by the older chemists, from a supposed resemblance in its crystals to sugar, or from their having a slight sweetness in the mouth. Sugar of lead, though poisonous, is useful in medicine, having a strongly detestive quality; and it is much employed in calico-printing.—3 *Fig.* sweet, honeyed, or soothing words; flattery employed to disguise something distasteful.—*Sugar of milk*, lactine (which see).—*Sugar of acorns*, quercite (which see).

Its average height is from 50 to 60 feet, with a diameter of from 12 to 18 inches. From its sap sugar is manufactured in considerable quantities in the United States and Canada. As the ascending sap is richest in sugar the trees are tapped in the early spring. Two holes about 20 inches from the ground are bored in the tree, and wooden spouts are driven into them, which convey the sap into troughs or pails placed on the ground. From the troughs it is conveyed to boilers, and manufactured into sugar on the spot. See **MAPLE**.

Sugar-mill (shu'gér-míl), *n.* A machine for pressing out the juice of the sugar-cane. It consists usually of three heavy rollers, placed horizontally and parallel to each other, one above and between the other two. These are driven by a steam-engine, by water, or by animal power. The canes are made to pass between the rollers, by which means they are crushed, and the juice ex-

pressed from them. The annexed illustration represents a form of sugar-mill in common use. The motive power is applied directly to the upper roller, and is communicated with an equal velocity by means of spur pinions, to the two lower rollers, which are brought nearly into contact with the upper, and the extremities of the axes of which are seen in the cut. The canes are spread upon the feeding-table regularly, and as nearly as possible at right angles to the axes of the rollers, and are first drawn downward between the upper and first lower roller, then upwards between the upper and second lower roller, being thus crushed so as to separate the liquor, which flows downwards into the hollow bed of the mill, and is then drawn off by a spout, while the empty canes are detached from the rollers, and guided to the floor of the mill by the delivering board.

Sulphamic (sul'fam'ik), *n.* Having sulphur and ammonium as the characteristic constituents.—*Sulphamic acid*, an acid, the ammonium salt of which is produced by the action of dry ammonia on dry sulphur trioxide. It may be regarded as sulphuric acid in which one OH group is replaced by NH₂; thus, SO₂ (OH) NH₂. It is a monobasic acid, forming salts called sulphamates; of these ammonium sulphamate, SO₂ (ONH₄) NH₂, is one of the best known.

Sulphate (sul'fat), *n.* [From *sulphur*.] A salt of sulphuric acid. Sulphuric acid is dibasic, forming two classes of sulphates, viz. *neutral sulphates*, in which the two hydrogen atoms of the acid are replaced by metal, and *acid sulphates*, in which one hydrogen atom only is so replaced. The general formula of the former class is M₂SO₄, and of the latter MHSO₄. (M represents a monovalent metal.) Of the sulphates, some are found native; some are very soluble, some sparingly soluble, and some insoluble. All those that are soluble are recognized in solution by the test of nitrate or chloride of barium, which causes a white precipitate of sulphate of barium, insoluble in acids. All the insoluble sulphates, when fused with carbonate of soda, yield sulphate of soda, which may be recognized as above. Some neutral sulphates occur in the anhydrous state, and others occur combined with water. The most important sulphates are—sulphate of aluminium and potassium, or alum; sulphate of ammonium, employed for making carbonate of ammonia; sulphate of copper, or blue vitriol, much used as an escharotic in surgery, and also used in dyeing and for preparing certain green pigments; sulphate of iron, or green vitriol, used in making ink, and very extensively in dyeing and calico-printing; it is also much used in medicine; sulphate of calcium, or gypsum; sulphate of magnesium, or Epsom salts; sulphate of manganese, used in calico-printing; sulphate of mercury, used in the preparation of corrosive sublimate and of calomel; bisulphate of potash, much used as a flux in mineral analysis; sulphate of sodium, or Glauber's salts; sulphate of quinine, much used in medicine; sulphate of zinc, or white vitriol, used in surgery, also in the preparation of drying oils for varnishes, and in the reserve or resist pastes of the calico-print. It forms with most bases crystallizable salts, called *sulphovinates*, which are all soluble.

Sulphur (sul'fer), *n.* [L. *sulfur*, *sulphur*.] 1. Sym. S. At. wt. 32. Brimstone, an elementary non-metallic combustible substance, which has been known from the earliest ages of the world. It occurs in great abundance in the mineral, sparingly in the vegetable, and still more sparingly in the animal kingdom. It occurs sometimes pure or merely mixed, and sometimes in chemical combination with oxygen and various metals, forming sulphates and sulphides. It is found in greatest abundance

and purity in the neighbourhood of volcanoes, modern or extinct, as in Sicily; and as an article of commerce, is chiefly imported from the Mediterranean. That which is manufactured in this country is obtained by the roasting of iron pyrites. It is commonly met with in two forms; that of a compact, brittle solid, and a fine powder. It is nearly tasteless, of a greenish yellow colour, and when rubbed or melted emits a peculiar odour. Its specific gravity is 1.99; it is insoluble in water, and not very readily soluble in alcohol, but is taken up by spirits of turpentine, by many oils, and by carbon disulphide. It is a non-conductor of electricity. It is readily melted and volatilized. It fuses at 232° Fahr., and between 232° and 280° it possesses the greatest degree of fluidity, and when cast into cylindrical moulds forms the common roll-sulphur of commerce. It possesses the peculiar property of solidifying at a higher degree, or when raised to 320°. Between 430° and 480° it is very tenacious. From 480° to its boiling-point (792°) it again becomes liquid. At 792° it rises in vapour, and in close vessels condenses in the form of a fine yellow powder, called *flowers of sulphur*. When sulphur is heated to at least 430°, and then poured into water, it becomes a ductile mass, and may be employed for taking the impressions of seals and medals. Sulphur exists in two distinct crystalline forms, and also as an amorphous variety; these modifications are characterized by differences in specific gravity, in solubility in various liquids, and in many other points. Sulphur combines with oxygen, hydrogen, chlorine, &c., forming various important compounds. It unites also with the metals, forming sulphides. It is of great importance in the arts, being employed in the manufacture of gunpowder, lucifer-matches, vulcanite, and sulphurous and sulphuric acids. It is also employed in medicine, and for various other purposes.—*Crude sulphur*, the result of the distillation of native sulphur.—*Sulphur group*, the elementary substances sulphur, selenium, and tellurium; all having a strong attraction for oxygen.—*Roll or stick sulphur*, sulphur refined and cast into wooden moulds.—2. Sulphuretted hydrogen (H₂S), a compound formed when hydrogen and sulphur come in contact in the nascent state. It is a transparent colourless gas, recognized by its peculiar fetid odour, resembling that of putrid eggs. It is very deleterious to animal life, and is often formed where animal matters or excrements putrefy. It is the active constituent of sulphureous mineral waters. It is also known by the name of *Hydrosulphuric Acid*, *Sulphydric Acid*, and *Hydrothionic Acid*. It is usually prepared by decomposing a metallic sulphide, especially sulphide of iron or of antimony, by means of hydrochloric or sulphuric acid.

Sulphuric (sul'fūr-ik), *a.* Pertaining to or obtained from sulphur.—*Sulphuric acid*, oil

of vitriol, a most important acid, discovered by Basil Valentine towards the close of the fifteenth century. It was formerly procured by the distillation of dried sulphate of iron, called *green vitriol*, whence the corrosive liquid which came over in the distillation, having an oily consistence, was called *oil of vitriol*. It is now prepared in this and most other countries by burning sulphur, or more frequently iron pyrites, in closed furnaces, and leading the fumes, mixed with oxides of nitrogen, into large leaden chambers, into which jets of steam are continuously sent. The oxides of nitrogen are produced by the action of sulphuric acid upon nitre contained in pots, which are placed between the sulphur ovens and the chambers. The sulphur dioxide takes away part of the oxygen from the oxides of nitrogen, which are again oxidized by the air in the chambers. The sulphur trioxide produced unites with the steam to form sulphuric acid. The acid produced in the chamber is condensed in leaden vessels until it reaches a certain gravity, when it is run into glass, or sometimes into platinum vessels, where the condensation is continued. Pure sulphuric acid is a dense, oily, colourless fluid, having, when strongly concentrated, a specific gravity of about 1.8. It is exceedingly acid and corrosive, decomposing all animal and vegetable substances by the aid of heat. It unites with alkaline substances, and separates most of the other acids from their combinations with the alkalis. It has a very great affinity for water, and unites with it in every proportion, producing great heat; it attracts moisture strongly from the atmosphere, becoming rapidly weaker if exposed. The sulphuric acid of commerce is never pure, but it may be purified by distillation. With bases sulphuric acid forms salts called sulphates, some of which are neutral and others acid. By concentrating sulphuric acid as far as is possible without decomposition, and cooling the liquid so obtained, crystals of the true acid, H₂SO₄, are formed. The ordinary acid is a hydrate of H₂SO₄, of varying composition. A form of sulphuric acid known as *Nordhausen acid* is prepared by heating green vitriol in closed vessels; it is a solution of sulphur trioxide in sulphuric acid (H₂SO₄.SO₃), or it may be regarded as *pyrosulphuric acid* (H₂S₂O₇). The best test of the presence of sulphuric acid, whether free or combined, is a soluble compound of barium. Thus, when a solution of chloride of barium is added to a liquid containing sulphuric acid it causes a white precipitate, viz. sulphate of barium, which is not only insoluble in water, but in the strongest acids. Of all the acids the sulphuric is the most extensively used in the arts, and is in fact the primary agent for obtaining almost all the others by disengaging them from their saline combinations. Its uses to the scientific chemist are innumerable. In medicine it is used in a diluted state as a refrigerant. See **SULPHATE**.—*Sulphuric ether*, ethylic, vinic, or ordinary ether—(C₂H₅)₂O—a colourless transparent liquid, of a pleasant smell and a pungent taste, extremely exhilarating, and producing a degree of intoxication when its vapour is inhaled by the nostrils. It is produced by distilling a mixture of equal weights of sulphuric acid and alcohol, and by various other means. Its specific gravity is 0.720. It is extremely volatile and highly inflammable; and its vapour, mixed with oxygen or atmospheric air, forms a very dangerous explosive mixture. It dissolves in 10 parts of water, and is miscible with alcohol and the fatty and volatile oils in all proportions. It is employed in medicine as a stimulant and antispasmodic. The vapour of ether has been administered with success to patients when about to undergo surgical operations, but it is now to a great extent superseded by chloroform. True sulphuric ether, known also as *sulphate of ethyl*—(C₂H₅)₂SO₄—is an oily liquid, of burning taste and ethereal odour, resembling that of peppermint, of sp. gr. 1.120, and almost incapable of being distilled without decomposition, as at a temperature of about 280° it resolves itself into alcohol, sulphurous acid, and olefiant gas.—*Sulphuric oxide*, or sulphur trioxide (SO₃), is a white crystalline body produced by the oxidation of sulphurous oxide (which see). When this oxide is thrown into water it combines rapidly with the latter to form sulphuric acid.

Sulphurous (sul'fēr-us), *a.* Made or impregnated with sulphur; like sulphur; containing sulphur. 'There's the sulphurous pit.' *Shak.*—*Sulphurous oxide*, a gas formed by the combustion of sulphur in air or dry oxygen. It is transparent and colourless, of a disagreeable taste, a pungent and suffocating odour, is fatal to life, and very injurious to vegetation. At 45°, under the pressure of two atmospheres, it becomes liquid, and also at 0° under the pressure of one atmosphere. It extinguishes flame, but is not itself inflammable. It has considerable bleaching properties, so that the fumes of burning sulphur are often used to whiten straw, and silk and cotton goods. This gas is also called *Sulphur Dioxide*; when led into water it forms *sulphurous acid* (H₂SO₃). This acid readily takes up oxygen, passing into sulphuric acid; it is dibasic, forming salts called sulphites.

of the equator it may be roughly said to include the months of June, July, and August. Astronomically considered, summer begins in the northern hemisphere when the sun enters Cancer, about the 21st of June, and continues for three months, till September 23d, during which time the sun, being north of the equator, shines more directly upon this part of the earth, which renders this the hottest period of the year. In latitudes south of the equator just the opposite takes place, or it is summer there when it is winter here. The entire year is also sometimes divided into summer and winter, the former signifying the warmer and the latter the colder part of the year.—2. A whole year; a twelve-month.

Sun (sun), *n.* [A. Sax. *sunne* (fem.), Icel. *O. I. G. and Goth. sunna* (Goth. also *sunno*), G. *sonne*, L.G. *sunne*, D. *zon*. There are kindred forms with final *l*, Icel. *sól*, Dan. and Sw. *söl*, also rarely A. Sax. *söl*; these forms coinciding with *L. sol*; also (with common interchange of *s* and *h*) Gr. *hēlios*, W. *haul*, Corn. *houl*, Armor. *heol*. From a root meaning to shine.] 1. The splendid orb or luminary which, being in or near the centre of our system of worlds, gives light and heat to all the planets, and is therefore the primary cause of all the motions and changes effected on the surface of our globe by those mighty agents. All the planets and comets of our system revolve round the sun as a common centre, at different distances and in different periods of time. Its mean apparent diameter is about 32 minutes, and its mean distance from the earth about 92,000,000 of miles. Its real diameter is 860,000 miles, and hence its volume is equivalent to about 14 million times the volume of our earth; but its mean density is only a fourth of that of the earth. It revolves on its axis from west to east in 25½ of our mean solar days, the axis being inclined at an angle of 82° 40' to the plane of the ecliptic. When viewed through powerful telescopes the sun's disc is observed to have large and perfectly black spots upon it, several of which are usually visible at once. These spots present the appearance of black irregular patches, and have been proved to be hollows in the luminous surface of the sun. (See *Solar spots* under *SOLAR*.) These spots appear and disappear very irregularly, some lasting for weeks and months, others only a day. Around the spots, and on other places, there are often masses brighter than the general surface, called *facule* or *torches*. The general surface itself is not uniform, but appears mottled, and made up of bright roundish patches, with soft edges, sprinkled irregularly on a less luminous background. The luminous surface of the sun is called the *photosphere*. The photosphere is overlaid by an atmosphere which is invisible under ordinary circumstances, but reveals itself to the spectroscopic, and at a total eclipse forms the white halo or *corona* which is seen surrounding the moon. Within the corona are seen oddly shaped masses of a red colour, projecting considerably at various points beyond the moon's edge, and these projections are united by a continuous belt of similar, though less vivid colour. This belt is called the *chromosphere*, and these reddish masses are great clouds or flames of incandescent hydrogen. The spectroscopic has shown the sun to be composed of substances identical, partly at least, with those composing the earth, as hydrogen, sodium, iron, magnesium. The matter is so intensely hot as to be largely in the state of vapour. The amount of light sent forth by the sun is not exactly measurable, but the amount of heat has been pretty accurately computed, and it is certainly enormous. It is equivalent in mechanical effect to the action of 7000 horse-power on every square foot of the solar surface, or to the combustion on every square foot of upwards of 13½ cwt. of coal per hour.—2. In popular usage, the sunshine; a sunny place; a place where the beams of the sun fall; as, to stand in the *sun*, that is, to stand where the direct rays of the sun fall.—3. Anything eminently splendid or luminous; that which is the chief source of light, honour, glory, or prosperity.

motion of the beam into a rotatory motion. In the annexed figure the sun wheel *a*, is a toothed wheel fixed fast to the axis of the fly-wheel, and the planet wheel *b* is a similar wheel bolted to the lower end of the connecting-rod *c*; it is retained in its orbit by a link at the back of both wheels. By the reciprocating motion of the connecting-rod the wheel *b* is compelled to circulate round the wheel *a*, and in so doing carries the latter along with it, communicating to the fly-wheel a velocity double of its own.—*Sun* forms the first element of many self-explanatory compounds: as *sun-bright*, *sun-clad*, *sun-dried*, *sun-like*, *sun-lit*, *sun-scorched*, &c.

Sun (sun), *v.t.* pret. & pp. *sunned*; ppr. *sunning*. To expose to the sun's rays; to warm or dry in the light of the sun; to insolate; as, to *sun* cloth; to *sun* grain. 'To *sun* thyself in open air.' *Dryden*.

are marked the directions of the shadow for the several hours of the day, their halves, quarters, &c. But the forms which may be

Sun-dial.—Face of Horizontal Dial, shadow pointing to one o'clock.

given to dials are almost infinite. The most common form is the horizontal dial, having the plane of the dial parallel to the horizon, and consequently making with the style an angle equal to the latitude of the place, since the style must always point to the north pole. The hour lines intersect each other at the point where the style intersects the dial plane, and the angles they make with one another and with the meridian line, or line for twelve o'clock, depend on the latitude. In vertical dials the position of these lines depends on the latitude and the aspect of the face.

But as we, under heaven, are supreme head,

—*Papal supremacy*, the authority, legislative, judicial, and executive, which the pope exercised over the churches of England, Scotland, and Ireland until the middle of the sixteenth century, when it was abolished, and which still continues to be more or less recognized in all countries whose inhabitants are in communion with the Church of Rome. *Regal supremacy*, the authority and jurisdiction which the sovereign of England exercises over the Church of England, as being the supreme head on earth of that church. This authority is not legislative, but judicial and executive only, and the most familiar form in which it appears is in the nomination to bishoprics and archbishoprics. Henry VIII. was first acknowledged supreme head of the church in 1532; and this supremacy was confirmed by parliament to him, his heirs, and successors, kings of this realm, in 1534. *Oath of supremacy*, in Great Britain, an oath denying the supremacy of the pope in ecclesiastical or temporal affairs in this realm. It was by many statutes required to be taken, along with the oath of allegiance and of abjuration, by persons in order to qualify themselves for office, &c.; but a greatly modified and simpler form of oath has now superseded them.

Sura (sû-ra), *n.* [Ar.] A chapter of the Koran.

These chapters were, it is asserted, given forth sometimes as a whole, sometimes in fragments, and often in single verses. Such fragments Mohammed, it is said, directed his adherents to enter 'in the *sura* which treated of such and such a subject.' If this tradition be authentic, it would indicate that Mohammed wished the Koran to be arranged according to its matter, and not chronologically; and hence the difficulty of assigning dates to each *sura*, or portion of a *sura*, is indelibly increased. *Brande & Cox.*

Or, a *surd* denotes the root of any quantity, when that quantity is not a complete power of the dimension required by the index of the root. Hence, the roots of such quantities cannot be expressed by rational numbers. Thus the square root of 2 (or $\sqrt{2}$), the cube root of 4 ($\sqrt[3]{4}$), the fourth root of 7 ($\sqrt[4]{7}$), &c., are *surds*, for they cannot be expressed by rational numbers. 2. 1. The swell of the sea which breaks upon the shore, or upon sandbanks or rocks.—

2. In agri. the bottom or conduit of a drain. [Local.]

Surface (sŭr'fas), *n.* [*Fr. surface*, from *sur*, upon, and *face*, or directly from *L. superflues*.] 1. The exterior part of anything that has length and breadth, one of the limits that terminates a solid, the superficies; outside; as, the *surface* of the earth; the *surface* of the sea, the *surface* of a diamond; the *surface* of the body; the *surface* of a cylinder; an even or an uneven *surface*. Popularly, *surface* is often used to signify, not merely the outside or exterior boundary of any substance, but also a certain thickness of the exterior material part. In this way we speak of the *surface* of the earth, the *surface* of the soil, of taking off the *surface* of anything, &c. 2. In geom. a superficies; that which has length and breadth only, and so distinguished from a *line*, which has length only, and from a *solid*, which has length, breadth, and thickness. The extremities of a surface are lines, and the intersections of one surface with another are also *lines*.—3. A plane surface is that in which any two points being taken the straight line between them lies wholly in that surface.

A surface which may be cut by a plane through any given point, so that the line of common section of the plane and surface may be a curve, is called a *curved surface*; as the surface of a sphere, cylinder, or cone. Surfaces are distinguished algebraically by the nature and order of their equations. Thus, we have surfaces of the first order, or plane surfaces, and surfaces of the second order, or curved surfaces. Surfaces are also distinguished by their mode of generation; thus the surface of a sphere is generated by the revolution of a semicircular arc about the diameter, which remains fixed. In *physics*, a surface is supposed to be composed of a number of material particles, placed together side by side, without any opening or interstice between them. Such a surface, therefore, cannot be said to be absolutely destitute of thickness, but may be regarded as a thin matter whose thickness is indefinitely small. *Tabular surface*, a surface generated by a circle of a given radius, which moves with its centre on a given curve, and its plane at right angles to the tangent of that curve. *Ruled surface*, a surface described by the motion of a straight line, which neither remains parallel to a given line nor always passes through a given point, as conoidal surfaces.—*Developable surface*, a surface that can be unwrapped in a plane without any doubling of parts over one another, or separation, as the surfaces of the cylinder and cone.—*Undevelopable surface*, a surface that cannot be developed in the plane. 3. Outward or external appearance; what appears on a slight or casual view or without examination; as, this arrangement, on the *surface*, was very advantageous. 4. In fact that part of the soil which is terminated by the bank prolonged, and the angle of the nearest bastion.

It usually consists of a large number of brass tubes united at their ends by means of a pair of flat steam-tight vessels, or of two sets of radiating tubes. This set of tubes is inclosed in a casing, through which a sufficient quantity of cold water is driven. The steam from the exhaust pipe is condensed as it passes through these tubes, and the condensed water is returned to the boiler.

They are remarkable for their dense plumage, extreme length of wing, and velocity of flight, while their feet and legs are comparatively weak. Their food consists of insects, which they catch in the air, and thus they pass more of their time upon the wing than most other birds. Their bill is short and very broad at the base, so that the gape is remarkably wide. They are found almost all over the world. In temperate climates the swallows are migratory birds, marking the arrival of spring by their coming, and giving notice that summer is over by their departure to warmer regions. The common species in Britain are the chimney swallow (*Hirundo rustica*), the house-martin (*H. urtica*), and the sand-martin (*H. riparia*). The chimney swallow has the tail very deeply forked, the two outside feathers being far longer than any of the others. It is about 8½ inches in length. The upper parts and a broad

bar across the breast are bluish black, the forehead and throat chestnut, the under surface white. The nest is cup-shaped,

The sand-martin is smaller than either of the above, brownish on the upper parts, white below, with the tail moderately forked. It makes its nest in steep sandy banks, excavating by means of its bill a gallery 18 inches or more in depth for the purpose. The purple martin (*H. purpurea*) is a very common species in North America, and is a great favourite in the northern parts, where, like the British species, it serves as a herald of spring. Several other species belong to America.

Swedenborgian (swē-den-bor'ji-an), *n.* One who holds the doctrines of the New Jerusalem Church as taught by Emanuel Swedenborg, a Swedish nobleman, born at Stockholm in 1689. He professed himself to be the founder of the New Jerusalem Church, alluding to the New Jerusalem spoken of in the book of the Revelation, and conceived that the members of this church were gifted with peculiar insight into spiritual things. The Swedenborgians believe that the regenerate man is in direct communication with angels and with heaven. They maintain that the sacred Scriptures contain three distinct senses, called celestial, spiritual, and natural, which are united by correspondences, and are accommodated respectively to particular classes, both of men and angels. They hold that there have been various general judgments ending particular dispensations of divine revelation. The last was in 1757, when Swedenborg received the office of teaching the doctrines of the new church promised in the Apocalypse. As this church is to be eternal there will be no other general judgment, but each individual is judged soon after death. There are numerous societies of them both in Great Britain and America.

In *logic*, a form of reasoning or argument, consisting of three propositions, of which the two first are called the *premises*, and the last the *conclusion*. In this argument the conclusion necessarily follows from the premises; so that if the two first propositions are true the conclusion must be true, and the argument amounts to demonstration. Thus, a plant has not the power of locomotion; an oak is a plant; therefore an oak has not the power of locomotion. These propositions are denominated the major, the minor, and the conclusion. The three propositions of a syllogism are made up of three ideas or terms, and these terms are called the *major*, the *minor*, and the *middle*. The subject of the conclusion is called the *minor* term; its predicate is the *major* term, and the middle term is that which shows the connection between the major and minor term in the conclusion; or it is that with which the major and minor terms are respectively compared. Syllogisms are divided by some into single, complex, conjunctive, &c., and by others into categorical, hypothetical, conditional, &c. What is called the *figure* of a syllogism is the proper disposition of the middle term with reference to the major and minor terms. The figures are by many logicians reckoned four, but the fourth is now usually considered as both unnatural and unnecessary, being only an awkward inversion of the first, to forms of which, indeed, all the other figures are held to be reducible. The mood of a syllogism is the designation of its three propositions, according to their quantity

and quality. The quantity and quality of propositions, in logic, are marked by arbitrary symbols, as A, E, I, O. Every assertion may be reduced to one of four forms—the universal affirmative, marked by A; the universal negative, marked by E; the particular affirmative, marked by I; and the particular negative, marked by O. From these, by combination, all syllogisms are derived. In order to remember the figures, certain mnemonic words have been long used by writers on logic; thus, under the first figure, we have Barbara, Celarent, Darii, Ferio; under the second, Cesare, Camestres, Festino, Baroko; under the third, Darapti, Disamis, Datisi, Felapton, Bocardo, Feriso; and under the fourth, Bramantip, Camenes, Dimaris, Fesapo, Fresison. (See these words.) Each of these words designates a particular mood. The rules of syllogism may be thus briefly expressed: (a) one at least of the premises must be affirmative, and one at least universal; (b) the middle term must enter universally in one of the premises; and (c) the conclusion must not speak of any term in a wider sense than it was spoken of in the premise in which it entered. A term universally spoken of is either the subject of a universal affirmative, or the predicate of any negative. Syllogisms are nothing else than reasoning reduced to form and method, and it is well to know, when an argument is presented in a puzzling or perplexing form, with perhaps a suppression of one of its essential propositions, how to supply the suppressed premises and put the argument into regular order; the truth or fallacy of the reasoning then become apparent at a glance.—2. burgh, for measuring the weight of the atmosphere by the compression of a column of gas. It consists of a glass tube about 15 inches long, having the lower end bent up like the tube of the wheel-barometer, each end being terminated by an elongated bulb. The upper end is hermetically sealed, but the lower end is left open. The upper part of the tube is filled with hydrogen gas, and the lower part with some fixed oil. The pressure of the atmosphere is exerted upon the surface of the oil, which is exposed to it in the turned-up open end of the tube. This pressure causes the oil to stand at a certain height in the tube, and to produce a certain compression in the column of hydrogen gas. As the atmospheric pressure becomes greater the oil will rise and the gas will be compressed into less space. The change in the bulk of the gas caused by a change in the atmospheric pressure is measured by a scale. The sympiesometer is sensitive, but inferior in accuracy to the common barometer. Written also *Sympiesometer*.

Synagogues were erected not only in towns and cities but also in the country, especially near rivers, that they might have water for their purifications and ceremonies. At the extreme east end of the building was the holy ark, containing copies of the Pentateuch; in front of this was a raised platform for the reader or preacher. The men sat on one side of the synagogue, the women on the other, a partition 5 or 6 feet high dividing them. The chief seats for which the scribes and Pharisees strove were situated near the east end.

The synagogue was governed by a council or college of elders, over whom was a president called the ruler of the synagogue. The service consisted of prayers, reading the Scriptures, and preaching and expounding of them. The chief ruler or one of the council might call upon any one present to address the people, or even a stranger might volunteer to speak. Properly defined, *synonyms* are words of the same language and the same grammatical class, identical in meaning; or, more generally, *synonyms* are words of the same language which are the precise equivalents of each other. And if a definition of this word in the singular be insisted on, we may say that a noun or other part of speech, identical in meaning with another word of the same language and the same grammatical class, is the *synonym* of that word; or, less specifically, a *synonym* is a word identical in meaning with another word of the same language and the same grammatical class. But though this is the proper definition of true *synonymy*, it is by no means the ordinary use of the term, which is gener-

ally applied to words not identical, but similar, in meaning. Both in popular literary acceptance, and as employed in special dictionaries of such words, *synonyms* are words sufficiently alike in general signification to be liable to be confounded, but yet so different in special definition as to require to be distinguished.

Syringe (sir'ing), *n.* [Gr. *syrinx*, *syngros*, a pipe, a tube, from *syzo*, to pipe or whistle.] A portable hydraulic instrument of the pump kind, commonly employed to draw in a quantity of water or other fluid, and to squirt or eject the same with violence. In its simplest form it consists of a small cylindrical tube with an air-tight piston fitted with a rod and handle. The lower end of the cylinder terminates in a small tube, which being immersed in any fluid, and the piston then drawn up, the fluid is forced into the body of the cylinder by the atmospheric pressure. By pushing back the piston to the bottom of the cylinder the contained fluid is expelled in a small jet. The syringe acts on the principle of the sucking-pump, and is used by surgeons, &c., for washing wounds, for injecting fluids into animal bodies, and other purposes. A larger form is used for watering plants, trees, &c. The syringe is also used as a pneumatic machine for condensing or exhausting the air in a close vessel, but for this purpose two valves are necessary.

Every work, both of nature and art, is a *system*; and, as every particular thing, both natural and artificial, is for some use or purpose out of and beyond itself, one may add to what has already been brought into the idea of a *system* its conclusiveness to this one or more ends. Let us instance in a watch. *Baker*.

The blood of reptiles is cold—that is to say, slightly warmer than the external medium—owing mainly to the fact that the pulmonary and *systemic* circulations are always directly connected together, either within the heart or in its immediate neighbourhood, so that the body is supplied with a mixture of venous and arterial blood in place of arterial blood alone. *H. Jambolanum* is extensively cultivated in the East Indies on account of its edible fruit, sometimes called Java plum by Europeans, but jamoon by the natives. It is of a rich purplish colour, and of a subastringent sweetish taste, which

is more agreeable to the native than to the European palate. The bark is astringent, and dyes a brown colour; the wood is hard and durable, and much employed.

Syzygy (si'zi-j'i), *n.* [Gr. *syzygia*—*syn*, together, and *zygon*, a yoke.] 1. In *astron.* the conjunction or opposition of a planet with the sun, or of any two of the heavenly bodies. T.

T is the twentieth letter of the English alphabet, a sharp mute consonant, closely allied to *d*, both being dentals. In forming it the tip of the tongue is pressed close to the root of the upper teeth, as may be perceived in uttering the syllables *at*, *ta*, *ot*, *to*. This is also the position of the tongue for the letter *d*, as in the syllables *ad*, *da*, *od*, *do*; but *d* is uttered with voice, whereas *t* is entirely non-vocal. In reality *t* can be hardly said to have any sound at all, its use, like that of the other sharp mutes *k* and *p*, being merely to modify the manner of uttering the vocal sound which precedes or follows it. When *t* is followed by *h* in the same syllable, as in *think*, *that*, *with*, the combination forms two distinct sounds—surd or breathed, as in *think*, and sonant or vocal, as in *that*. These sounds were represented by two characters in Anglo-Saxon and Old English, and it is a pity the old letters were given up. The letters *t* before a vowel, and unaccented, usually pass into the sound of *sh*, as in *nation*, *motion*, *partial*, which are pronounced *nashon*, *moshon*, *parshal*. In this case *t* loses entirely its proper sound or use, and being blended with the subsequent letter a new sound results from the combination, which is in fact a simple sound. If *s* or *z* precede *t* (as in *mixture*, *question*), *t* retains its own sound, though in this case many speakers soften it to *ch* as in *church*, as they also do in such words as *mixture*, *posture*. In comparing words common to the Indo-European tongues we find that (as formulated by Grimm's law) *t* in English (as also in Dutch, Icelandic, Gothic, &c.) corresponds to *d* in Latin, Greek, and Sanskrit, and to *s* or *z* in German. Thus *E. tooth* = *L. dens*, *dentis*, Gr. (*odontos*, (*odontos*, Skr. *dant*, *G. zahm*; *E. foot* = *L. pes* (*pes*), *pedis*, Gr. *pous*, *podos*, Skr. *paita*, *G. fuss*; *E. two* = *L. duo*, Gr. *dyo*, Skr. *dva*, *G. zwei*; *E. to eat* = *L. edo*, Gr. *edo*, Skr. *ad*, *G. essen*, and so on. An *s* before *t*, however, hinders this change from taking place, and hence the *t* in *E. stand* appears also in *L. sto*, Gr. *histemi*, and *G. stehen*. The English *th*, on the other hand, answers to *t* in Latin, Greek, and Sanskrit, and to *d* in German; thus *E. thou* = *L. et tu*, Skr. *team*, *G. du*; *E. three* = *L. tres*, Gr. *treis*, Skr. *tri*, *G. drei*. Hence it comes that *G. tag* = *E. day*; *gut* = *good*, *wasser* = *water*, and *zahm* = *spense*. In some Latin words *d* has been changed to *t*, hence *t* in *E. tear* (*n.*) = *t* in *L. lacrima* (for *lacrima*), Fr. *larme*, a tear. A final *t* has become attached to many English words to which it does not properly belong, this being particularly the case after *n* and *s*, as in *tyrant*, *pheasant*, *ancient*, *amidst*, *whilst*, *against*, &c. It has sometimes dropped out, as in *best*, *last*; so *th* has disappeared from *worship*. This letter is often doubled in the middle of words, seldom at the end, as in *butt*, *mitt*. *T* is often used to denote things of this form, as the *T*-palace in Mantua. See **T-BANDAGE**, **T-BEARD**, **T-CLOTH**, **T-IKON**, **T-JOINT**, **T-SQUARE**.—*To a T*, exactly, with the utmost exactness; as, to suit or fit to a *T*. The allusion is to a mechanic's *T*-square, by which accuracy in making angles, &c., is secured. [Familiar.]

We could manage this matter to a *T*. *Sterne.*

shorter. It was at first chiefly worn by the military, but afterwards became an ordinary article of dress among other classes in France and England in the middle ages. It is used also in cases of bilious vomitings, bloody flux, piles, &c. Its optical properties are peculiar, inasmuch as it exhibits the lowest refracting power of all known substances. The sweet juice of the bamboo stalks has also been called *tabasheer*.

In meaning 2 the origin is doubtful.] 1. The name given to a kind of rich silk and other stuffs watered or figured by being passed through a calender, the rollers of which are variously engraved. "Brocades, and laces, and tabbies, and gauzes." *Swift*.—2. In the common tables of logarithms the logarithms of all numbers from 1 to 10,000 can be found by inspection, but by the aid of the tabular differences the logarithms of numbers between 10,000 and 1,000,000 may be found. Also, by the aid of the same differences the number corresponding to any given logarithm can be found to five or six places. In logarithmic tables of sines, tangents, secants, cosines, cotangents, and cosecants there are three columns of tabular differences in each page. The first of these is placed between the sines and cosecants, the second between the tangents and cotangents, and the third between the secants and cosines. These numbers are the differences between the logarithms on the left hand, against which they are placed, and the next lower, increased in the proportion of 100 to 60. The use of these differences is to facilitate the finding of the logarithmic sine, tangent, secant, &c., for any given degrees, minutes, and seconds, or the degrees, minutes, and seconds corresponding to any given logarithmic sine, tangent, secant, &c.

Its prevailing colours are white, apple-green, and yellow. There are three principal varieties of talc, *common*, *earthy*, and *indurated*. Talc is a silicate of magnesium, with small quantities of potash, alumina, oxide of iron, and water. It is used in many parts of India and China as a substitute for window-glass; indurated talc is used for tracing lines on wood, cloth, &c., instead of chalk. The name of a weight and denomination of money among the ancient Greeks, and also applied by Greek writers and their translators to various standard weights and denominations of money of different nations; the weight and value differing in the various nations and at various times. The Attic talent as a weight contained 60 Attic minæ, or 6000 Attic drachmæ, equal to 59 lbs. 11 oz. English troy weight. As a denomination of silver money it was equal to £243. 15s. The great talent of the Romans is computed to be equal to £93, 6s. 8d. sterling, and the little talent to £75 sterling. A Hebrew weight and denomination of money, equivalent to 3000 shekels, also receives this name. As a weight, therefore, it was equal to about 93½ lbs. avoirdupois; as a denomination of silver it has been variously estimated at from £340 to £396, the higher value being that given by the latest authorities.—2. A gift, endowment, or faculty; some peculiar faculty, ability, or qualification natural or acquired. 'Wit, knowledge, or any other talent whatsoever.' *Addison.*

3. Mental endowments or capacities of a superior kind; general mental power: used in this sense either in singular or in plural; as, a man of talents; a man of great talent. This and the previous application of the word are probably borrowed from the Scriptural parable of the talents, Mat. xxv. Talented (tal'ent-ed), *a.* Furnished with talents or great mental powers; possessing talents or endowments [This word, as shown by the first quotation below, was introduced long ago, but seems not to have been in common use till quite recent times.

Coleridge and others have strongly objected to it (the former calling it 'a vile and barbarous vocable'), but without any good reason. The chief objection to it has been that it is a 'pseudo-participle,' a participle without a verb corresponding to it, but there are many words of exactly analogous formation in quite good usage; comp. *gifted, lettered, turreted, booted, bearded, shipped, landed, &c.* Mr. Fitzedward Hall instances *untalented* and *untalented* from Richardson.]

What a miserable and restless thing ambition is, when one *talented* but as a common person, yet, by the favour of his prince, hath gotten that interest, that in a sort all the keys of England hang at his girdle. *Asp. Sibot* (1592-1633).

The way in which *talented* and many of its fellows were once frequently used shows that these words, to the consciousness of our ancestors, began with being strictly participles. At present they have the function of participial adjectives; and, what between their distinctive termination and their history, they are, therefore, to be considered, on scientific principles, as developments from ideal verbs. The analogy on which they are formed is, further, so well established, that, whatever *Coleridge* dogmatized in his haste, 'mere convenience' is quite ground enough to justify us in coining terms on the same model whenever they may be really required.

Fitzedward Hall.

Tally (tal'i), *n.* [*Fr. taille*, a tally, a cut, a cutting, from *tallier*, to cut. See RETAIL.]

1. A piece of wood on which notches or scores are cut, as the marks of number. In purchasing and selling it was customary for traders to have two sticks, or one stick cleft into two parts, and to mark with scores or notches on each the number or quantity of goods delivered, or what was due between debtor and creditor, the seller or creditor keeping one stick, and the purchaser or debtor the other. Before the use of writing, or before writing became general, this or something like it was the usual method of keeping accounts. In the exchequer tallies were formerly used, which answered the purpose of receipts as well as simple records of matters of account. Hence the origin of exchequer bills. In former times of financial difficulty, from the period of the Norman conquest the practice had been to issue exchequer tallies. An exchequer tally was an account of a sum of money lent to the government, or of a sum for which the government would be responsible. The tally itself consisted of a squared rod of hazel or other wood, having on one side notches, indicating the sum for which the tally was an acknowledgment. On two other sides opposite to each other, the amount of the sum, the name of the payer, and the date of the transaction, were written by an officer called the writer of the tallies. This being done the rod was then cleft longitudinally in such a manner that each piece retained one of the written sides, and one half of every notch cut in the tally. One of these parts, the *counterstock*, was kept in the exchequer, and the other, the *stock*, only issued. When the part issued was returned to the exchequer (usually in payment of taxes) the two parts were compared, as a check against fraudulent imitation. This ancient system was abolished by 25 Geo. III. lxxxii.; and by 4 and 5 Will. IV. xv. all the old tallies were ordered to be destroyed. The size of the notches made on the tallies varied with the amount. The notch for £100 was the breadth of a thumb; for £1 the breadth of a barleycorn. A penny was indicated by a slight slit.—2. Anything made to suit or correspond to another.

That they were fram'd the tallies for each other. *Pope*.

Tangent (tan'jent), *n.* [L. *tangens*, *tangentis*, pp. from *l. tangere*, to touch. akin *tact*.]

In *geom.* a straight line which touches or meets a circle or curve in one point, and which being produced does not cut it, as A, B, C, D, E, F in fig. 1. Euclid has shown that the straight line drawn at right angles to the diameter of a circle, from the extremity of it, is a tangent to the circle. In *trigon.* the tangent of an arc or angle is a straight line touching the circle of which the arc is a part, at one extremity of the arc, and meeting the diameter passing through the other extremity. Thus, in fig. 2, let A H be a straight line drawn touching the circle A D E at A, one extremity of the arc A B, and meeting the diameter I B produced, which passes through the other extremity B in the point H; then A H is the tangent of the arc A B, or of the angle A C B, of which A B is the measure. The tangent of an arc or angle is also the tangent of its supplement. Thus, A H is the tangent of the supplement A I, or of the angle A C I; for it is easy to see that the definition above given applies equally to the arc A B and to the arc A I. The arc and its tangent have always a certain relation to each other; and when the one is given in parts of the radius, the other can always be computed by means of an infinite series. For trigonometrical purposes tangents for every arc from 0 degrees to 90 degrees, as well as sines, cosines, &c., have been calculated with reference to a radius of a certain length, and these or their logarithms formed into tables. In the higher geometry the word tangent is not limited to straight lines, but is also applied to curves in contact with other curves, and also to surfaces.—Method of tangents,

of the supplement A I, or of the angle A C I; for it is easy to see that the definition above given applies equally to the arc A B and to the arc A I. The arc and its tangent have always a certain relation to each other; and when the one is given in parts of the radius, the other can always be computed by means of an infinite series. For trigonometrical purposes tangents for every arc from 0 degrees to 90 degrees, as well as sines, cosines, &c., have been calculated with reference to a radius of a certain length, and these or their logarithms formed into tables. In the higher geometry the word tangent is not limited to straight lines, but is also applied to curves in contact with other curves, and also to surfaces.—Method of tangents,

the name given to the calculus in its early period. When the equation of a curve is given, and it is required to determine the tangent at any point, this is called the *direct method of tangents*; and when the subtangent to a curve, at any point, is given, and it is required to determine the equation of the curve, this is termed the *inverse method of tangents*. The above terms are synonymous with the differential and integral calculus.—*Natural tangents*, tangents expressed by natural numbers.—*Artificial tangents*, tangents expressed by logarithms.—To go or fly off at a tangent, to break off suddenly from one line of action, train of thought, or the like, and go on to something else.

From Dodson and Foggy's mind flew off at a tangent to the very centre of the history of the queer client. Dickens.

The seed was pounded and a small piece swallowed by each person to be tried. According to this custom the right of succession was not in the individual, but in the family to which he belonged; that is, succession was hereditary in the family, but elective in the individual. The primitive intention seems to have been that the inheritance should descend to the oldest or most worthy of the blood and name of the deceased. This was in reality giving it to the strongest, and the practice often occasioned bloody wars in families.

They were subject to the law of *tanistry*, of which the principle is defined to be, that the demense lands and dignity of chieftainship descended to the eldest and most worthy of the same blood. *Hallam*.

Tannic (tan'ik), *a.* Applied to a peculiar acid which exists in every part of all species of oak, especially in the bark, but is found in greatest quantity in gall-nuts. Tannic acid, when pure, is nearly white, and not at all crystalline. It is very soluble in water, and has a most astringent taste, without bitterness. It combines with animal gelatine, forming an insoluble curdy precipitate which has been called *tannogelatin*. It derives its name from its property of combining with the skins of animals and converting them into leather, or tanning them. It is the active principle in almost all astringent vegetables. The name tannic acid is generally applied to what is really a mixture of several substances. Called also *Quercitanic*.

Tanning (tan'ing), *n.* 1. The practice, operation, and art of converting the raw hides and skins of animals into leather by effecting a chemical combination between the gelatine of which they principally consist and the astringent vegetable principle called tannic acid or tannin. The object of the tanning process is to produce such a chemical change in skins as may render them unalterable by those agents which tend to decompose them in their natural state, and in connection with the subsequent operations of currying or dressing to bring them into a state of pliability and impermeability to water which may adapt them for the many useful purposes to which leather is

applied. The larger and heavier skins subjected to the tanning process, as those of buffaloes, bulls, oxen, and cows, are technically called *hides*; while those of smaller animals, as calves, sheep, and goats, are called *skins*. After being cleared of the hair, wool, and fleshy parts, by the aid of lime, scraping, and other means, the skins are usually steeped in an infusion of ground oak bark, which supplies the astringent or tanning principle, and thus converts them into leather. Different tanners, however, vary much in the mode of conducting the process of tanning, and also the skins intended for different kinds of leather require to be treated differently. Various improvements have been made in the process of tanning, by which time and labour are much reduced; but it is found that the slow process followed by the old tanners produces leather far superior to that produced by quick processes.—2. Appearance or hue of a brown colour produced on the skin by the action of the sun.

Diseases and distempers, incident to our faces, are industriously to be cured without any thought or blame of pride; as flushings, redness, inflammation, pimples, freckles, ruggedness, *tanning*, and the like.

Tape-worm (táp'werm), *n.* [From their resemblance in shape to a tape.] The name common to certain internal parasites (Entozoa) constituting the order Cestodea or Tenuaria of the sub-kingdom Anneloidea, found in the mature state in the alimentary canal of warm-blooded vertebrates. Tape-worms are composed of a number of flattened joints or segments, the anterior of which, or head (which is the true animal), is furnished with a circle of hooks and suckers, which enable it to maintain its hold on the mucous membrane of the intestines of its host. The other segments, called *proglottides*, are simply generative organs budded off by the head, the oldest being furthest removed from it, and each containing within mature male and female organs. The tape-worm has neither mouth nor digestive organs, nutrition being effected by absorption through the skin. The length of the animal varies from a few inches to several yards. The ova do not undergo development in the animal in which the adult exists. They require to be swallowed by some other warm-blooded vertebrate, the ripe proglottides being expelled from the bowel of the host with all their contained ova fertilized. The segments or proglottides decompose and liberate the ova, which are covered with a capsule. After being swallowed the capsule bursts and an embryo, called a *proscœlex*, is liberated. This embryo, by means of spines, perforates the tissues of some contiguous organ, or of a blood-vessel, in the latter case being carried by the blood to some solid part of the body, as the liver or brain, where it surrounds itself with a cyst, and develops a vesicle containing a fluid. It is now called a *scolex* or *hydratid*, and formerly was known as the *cystic worm*. The scolex is incapable of further development till swallowed and received a second time into the alimentary canal of a warm-blooded vertebrate. Here it becomes the head of the true tape-worm, from which proglottides are developed posteriorly by gemination, and we have the adult animal with which the cycle begins. Eight true tape-worms occur in man, *Tenia solium*, the cystic form of which produces the measles of the pig, being the most common. Another, *T. mediocanellata*, is developed from the scolex, which causes measles in the ox. The tape-worm of the dog, *T. serrata*, is the adult form of the scolex which produces staggers in sheep. *T. Echinococcus* of the dog produces hydratids in man, through the development in man of its immature young.

Another American species has been discovered in the Cordilleras, the back of which is covered with hair, and the bones of the nose more elongated and

A conical cavity is dug in the ground, with a cast-iron pan at the bottom, from which leads a funnel. Billets of wood (such as pine or fir) are thrown into this cavity, and being covered with turf are slowly burned without flame. The tar which exudes during combustion is conducted off through the funnel. In this country wood-tar is chiefly obtained as a by-product in the destructive distillation of wood for the manufacture of wood-vinegar (pyroligneous acid) and wood-spirit (methyl alcohol). It has an acid reaction, and contains various liquid matters of which the principal are methyl-acetate, acetone, hydrocarbons of the benzene series, and a number of oxidized compounds, as carbolic acid. Taraffin, anthracene, naphthalene, chrysene, &c., are found among its solid products. It possesses valuable antiseptic properties, owing to the creosote it contains, and is used extensively for coating and preserving timber and iron in exposed situations, and for impregnating ships' ropes and cordage. Coal-tar is extensively obtained in Britain in the process of gas manufacture. It is a very valuable substance, in as much as the compounds obtained from it form the starting-points in so many chemical manufactures. See COAL-TAR. — 2. Tartar (tar'tar), n. [Fr. *tartre*. It. and Sp. *tartaro*, L. L. *tartarum*, the hard deposit in wine casks. 'It is called tartar,' says Paracelsus, 'because it produces oil, water, tincture, and salt, which burn the patient as Tartarus (hell) does.' Another derivation is from Ar. *doudar*, sediment, lees, dregs.] Impure acid tartrate of potassium, called also *argal* or *argol*, deposited from wines incompletely fermented, and adhering to the sides of the casks in the form of a hard crust, varying from pale pink to dark red according as it has separated from white or red wines. When tartar is purified it is quite white, and forms cream of tartar, which is much used in dyeing, and also in medicine as a laxative and diuretic. See CREAM.—Salt of tartar, carbonate of potassium obtained by calcining cream of tartar.—Soluble tartar, neutral tartrate of potassium salt, obtained by adding cream of tartar to a hot solution of carbonate of potassium till all effervescence ceases. It has a mild saline, somewhat bitter taste, and is used as a laxative.—Tartar emetic, a double tartrate of potassium and antimony, an important compound used in medicine as an emetic, purgative, diaphoretic, sedative, febrifuge, and counter-irritant.—Tartar of the teeth, an earthy-like substance which occasionally concretes upon the teeth, and is deposited from the

saliva. It consists of salivary mucus, animal matter, and phosphate of lime.

Tartar (tar'tar), n. [A corruption of *Tutar*. When, in the reign of St. Louis of France, the hordes of the Tatar race were devastating Eastern Europe, news of their ravages were brought to the pious king, who exclaimed thereupon with horror, 'Well may they be called Tartars, for their deeds are those of fiends from Tartarus.' The appositeness of the appellation thus metamorphosed made it be received, and from that time French authors—and after them the rest of Europe—have called the Tartars, *Tartars*.] 1. A native of Tartary; a name rather loosely applied to members of various Mongolian or Turanian peoples in Asia and Europe.—2. A name given to couriers employed by the Ottoman Porte, and by the European ambassadors in Constantinople.—3. Tartaric (tar-tá-rik), a. Of, pertaining to, or obtained from tartar.—Tartaric acid ($C_4H_4O_6$), the acid of tartar. It exists in grape juice, in tamarinds, and several other fruits; but principally in bitartrate of potassium, or cream of tartar, from which it is usually obtained. It crystallizes in large rhombic prisms, transparent and colourless, and very soluble in water. It is inodorous and very sour to the taste. A high temperature decomposes it, giving rise to several new products. The solution of tartaric acid acts with facility upon those metals which decompose water, as iron and zinc. Tartaric acid is dibasic; its salts are called *tartrates*. Tartaric acid has a most remarkable disposition to form double salts, as the tartrate of potassium and sodium or Rochelle salts; the tartrate of potassium and antimony, or tartar emetic. There are five modifications of tartaric acid, characterized chiefly by the differences in the action exerted by them upon a ray of polarized light; such as dextro-ordinary tartaric acid, levo-tartaric acid para-tartaric or racemic acid, meso-tartaric acid, and meta-tartaric acid. Tartaric acid is largely employed as a discharge in calico-printing, and for making soda-powders. In medicine it is used in small doses as a refrigerant.

It depends on the fact that a piece of carbon introduced into the course of an electric current offers a resistance to the passage of the current, which diminishes in a very marked degree in proportion to the amount of pressure exerted on the carbon. A small disc of carbon and another of vulcanite are held together between two platinum buttons, which may be brought into connection with a galvanic battery, and a strip of some substance like gelatine, which contracts and expands with great readiness, is so placed that by its variations in magnitude it varies the pressure on one of the platinum buttons, and hence on the carbon disc. The variations thus produced in the force of the electric current are measured by a very delicate galvanometer, which is also placed in the circuit. So delicate is the instrument that the heat of the hand held a few inches off causes a deflection of the needle; while by a slight alteration in form the weight and vital heat of the minutest insect may be determined.

among civilized nations. It consists in marking the skin with punctures or incisions, and introducing into the wounds coloured liquids, gunpowder, or the like, so as to produce an indelible stain, so that in this way a variety of figures may be produced on the face and other parts of the body. Taylor's Theorem. A formula of most extensive application in analysis, discovered by Dr. Brook Taylor, and published by him in 1715. It is to the following effect. Let u represent any function whatever of the variable quantity x ; then if x receive any increment, as h , let u become u' , then we shall have $u' = u + \frac{du}{dx} \cdot h + \frac{d^2u}{dx^2} \cdot \frac{h^2}{1 \cdot 2} + \frac{d^3u}{dx^3} \cdot \frac{h^3}{1 \cdot 2 \cdot 3} + \frac{d^4u}{dx^4} \cdot \frac{h^4}{1 \cdot 2 \cdot 3 \cdot 4} + \&c.$, where d represents the differential of the function u . The great value of this theorem was overlooked till it was made the basis of the differential and integral calculus by Lagrange in 1772.

It consists chiefly of silica with a little alumina, lime, and oxide of iron, and about 7 per cent of vegetable mould, of which 2-45 is nitrogen gas. Tea (tē), *n.* [Fr. *thé*, from Chinese *tha*, *the*, *tea*, *tea*.] 1. The dried leaves of *Thea sinensis* or *chinensis* (the tea-plant), nat. order Ternstroemiaceæ, extensively cultivated in China; also the plant itself. Teas are in commerce all brought under two distinct terms, *green teas* and *black teas*, and it was at one time believed that these were the products of two different species of *Thea*, black tea of *T. Bohea*, and green tea of *T. viridis*, now regarded by botanists as mere varieties of *T. sinensis*. Though the products of the same species, black and green teas are mainly the growth of different districts of China, but the two varieties may be produced in either district, the difference being attained by diverse methods of preparation. (See *THEA*.) The black teas include *bohea*, *congou*, *souchong*, and *pekoe*; the green teas *twankay*, *hysonskin*, *young hyson*, *hyson*, *imperial*, and *gunpowder*. An infusion of tea as a beverage has slight nutritive value, but it increases respiratory action, and seems to have a decidedly stimulative and restorative action on the nervous system, due to the essential oil and theine it contains, whilst the tannin which is also present is an astringent. The use of tea in this country dates from the middle of the seventeenth century. The following advertisement appeared in the *Mercurius Politicus* of Sept. 30, 1658. 'That excellent and by all physicians approved China drink called by the Chinese *Tcha*, and by other nations *ay*, alias *tee*, is sold at the Sultana Head Coffee House, London.' An entry of Pepys's *Diary* in 1660 runs: 'I did send for a cup of tea, a China drink, of which I had never drunk before.' Substitutes for tea have been found in the dried leaves of a number of plants, some of which contain the same stimulating quality, and to which the name tea has consequently been applied. See the end of this article.—2. A decoction or infusion of tea leaves in boiling water, used as a beverage, which in this country is generally mixed with a little milk or cream and sweetened with sugar.—3. Any infusion or decoction of vegetables for drinking; as, sage tea; chamomile tea, &c.—4. A soup or extract of beef; as, beef-tea. See *BEEF-TEA*.—5. A drop or small quantity of the limpid fluid secreted by the lachrymal gland, and appearing in the eyes or flowing from them. The lachrymal fluid serves to moisten the cornea and preserve its transparency, and to remove any dust or fine substance that enters the eye and gives pain. The normally secreted fluid, after performing its ordinary functions, passes through the lachrymal ducts and sac into the nasal channels. Moral and physical causes, however, as strong passion (grief, sorrow, joy), uncontrollable laughter, pain, especially in the eye itself, increase the secretion considerably, and when the lachrymal duct does not suffice to carry it off it runs over the eyelids. For this purpose the heads are fixed round the circumference of a large broad wheel or drum so as to form a kind of brush. The wheel is made to turn round while the cloth is held against the brush thus formed, and the fine hooked awn of the teasel readily insinuates itself into the web, and draws out with it some of the fine fibres of the wool. By a succession of decrees and enactments these tithes were generally rendered redeemable at a fixed valuation, but the clergy have now no right to the teinds beyond a suitable provision, called a stipend; so that teinds may now be described as that portion of the estates of the laity which is liable to be assessed for the stipend of the clergy of the Established Church. Telegram (tē'-lē-gram), *n.* [Gr. *tēle*, far, and *gramma*, what is written, from *graphō*, to write. The word is said to have been coined in America in 1852, and Greek scholars objected to it as barbarous. *Graphō*, when compounded with anything but a preposition, becomes *graphōs*; therefore, compounded with *tēle*, the verb would be *tēle-graphōs*, and the noun from it *telegraphēma*, the English representative of which would be *telegraphemē*. The superior compactness of the illicit word, however, and the analogy of such forms as *chronogram*, *logogram*, *monogram*, enabled it to carry the day.] A communication sent by telegraph; a telegraphic message or despatch.

It is astonishing to see how rapidly a word is formed and takes root, if it expresses something of the so-called business of life. We all remember the introduction of the word *telegram* during the Crimean war, as distinguished from *telegraph*, which had previously, though certainly not etymologically, been used in both significations. *Chambers's Journal.*

And then there is, as against the exact, but surfeiting 'telegraphemē,' our lawless *telegram*, to which is strictly applicable the maxim of the civilians, as regards a clandestine marriage: '*Fieri non debuit, sed facta valet.*' *Fitzward Hall.*

—To *milk a telegram*, surreptitiously to make use of a telegram designed for another. [Slang.]

Telegraphic (tē'-lē-grāf'ik), *a.* Of or pertaining to a telegram; having the characteristics of a telegram; hence, brief; concise; succinct. [New and rare.]

Telegraph (tē'-lē-grāf), *n.* [Gr. *tēle*, far, at a distance, and *graphō*, to write.] 1. A general name for any instrument or apparatus for conveying intelligence beyond the limits of distance at which the voice is audible, the idea of speed being also implied. Thus the name used to be given to a semaphore or other signalling apparatus. The word, however, is now usually restricted in its application to the electric telegraph, which from its power of rapidly conveying elaborate communications to the greatest distances has thrown all others into the shade. The electric telegraph, as comprising the entire system of apparatus for transmitting intelligence by electricity, consists essentially (1) of a battery or other source of electric power; (2) of a line-wire or conductor for conveying the electric current from one station to another; (3) of the apparatus for transmitting, interrupting, and if necessary reversing the current at pleasure; and (4) of the indicator or signalling instrument. For the chief forms of battery in use see under **GALVANIC**. The line-wires for overhead lines are usually of iron, protected from atmospheric influence by galvanizing or by being varnished with boiled linseed-oil, a coating of tar, or other means, and are supported upon posts, to which they are attached by insulators. (See **INSULATOR**.) In underground lines the wires are insulated by a gutta-percha or other non-conducting covering, and inclosed in iron or lead pipes. A description of the line-conductor in submarine telegraphs will be found under **CABLE**. The battery and line-wire are common to all telegraphic systems; it is in the method of producing the signals that the great variation exists; but in all of them advantage has been taken of one or other of the three following properties of the current: (1) its power of producing the deflection of a magnetic needle, as in the galvanometer (which see); (2) its power of temporarily magnetizing soft iron; and (3) its power of producing chemical decomposition. The *needle-telegraph* of Cooke and Wheatstone is an application of the first of these properties. In it a pair of needles is used, one of which, being magnetized, is placed within a multiplying coil, the other appearing on the dial of the instrument.

The plane of the coil is vertical; the needles hang on horizontal axes. The dial needle deflects its upper end to the right or left in accordance with the direction of the current, and it is by combinations of these deflections that the letters, &c., are formed. A double-needle telegraph, consisting of two single needle-instruments, has been used; but although it gives great increase of speed of transmission, from its expense, requiring the maintenance of two systems of line-wires, it can never be popular. The needle-telegraph was never adopted out of England, and even here the Morse has been generally substituted for it. Its transmitting instrument is a reversing key, worked by a handle, which appears on the instrument below the dial-needle. The turning of this handle in one direction or the other gives rise to a current of electricity from the battery, which passes through the instruments of both receiver and sender. The attention of the receiver is called by the preliminary sounding of an electric bell. The *electro-magnetic* instrument of Professor Morse is an application of the second of the above properties. By means of an electro-magnet, an armature which is attracted when the magnet is temporarily magnetized, a lever moved by the armature, and a style which moves with the lever, this instrument impresses a message in dots and dashes on a ribbon of moving paper. (See **MORSE-ALPHABET**.) A modification of this instrument, called a *sounder*, in which the lever makes audible sounds by coming in contact with a brass rod, indicates the message by the length of the strokes produced. Frequently the Morse is simultaneously a recorder and sounder. It being necessary that this instrument should produce sharp and distinct impressions, and the current being weak for stages over 50 miles, a relay is added to it in the case of longer distances. (See **RELAY**.) The transmitting instrument is a lever, which, on being pressed, permits the current from the battery to flow into the line-wire during the time the contact is made. Both on account of its intrinsic merits and for the sake of uniformity the Morse is the most extensively used system, being that in use in America and on the Continent of Europe, and being also largely employed in Britain. Wheatstone's 'universal telegraph' is also one in extensive use. The currents employed are magneto-electric, and are alternately positive and negative. They produce successive reversals of polarity in an electro-magnet, which acts upon a light steel magnet and causes it to rotate through a large angle first in one direction and then in the opposite. Each of these rotations causes a ratchet-wheel to advance one tooth, and this causes the pointer to advance one letter. At the same time the turning of the handle by which the currents are generated causes the pointer of the sending instrument to advance one letter for each current sent, so that the pointers at the two stations indicate the same letter. The same dial which serves for sending also serves for receiving. It is surrounded by a number of keys or buttons, and when any letter is to be sent its key is depressed, the operator continuing all the while to turn the handle for generating currents. The *electro-chemical telegraph* of Alexander Bain of Edinburgh takes advantage of the third of the above-mentioned properties of the current. Upon a metallic disc, which is carried round by clockwork, is laid a sheet of paper, prepared by having been dipped in a solution of prussiate of potash, nitric acid, and ammonia, over which rests a screw-plate, serving to guide a pen, consisting of a piece of fine steel, connected with the positive pole of the battery, the metallic disc being connected with the negative. The transmitting instrument is that of Morse. When a current is transmitted it decomposes the prussiate of potash in passing through the moistened paper, and the acid, uniting with the iron style at the positive electrode, forms ferrocyanide of iron or Prussian blue, leaving a distinct blue trace upon the paper moving under it. There are many more instruments, modifications of one or other of the above. Instruments, as Hughes' telegraph, have been invented which print the message in Roman characters, but as yet they have been little used. *Autographic telegraphs*, by which writing or a design can be produced in facsimile have also been invented. Cassell's telegraph effects this end by the use of a

The plane of the coil is vertical; the needles hang on horizontal axes. The dial needle deflects its upper end to the right or left in accordance with the direction of the current, and it is by combinations of these deflections that the letters, &c., are formed. A double-needle telegraph, consisting of two single needle-instruments, has been used; but although it gives great increase of speed of transmission, from its expense, requiring the maintenance of two systems of line-wires, it can never be popular. The needle-telegraph was never adopted out of England, and even here the Morse has been generally substituted for it. Its transmitting instrument is a reversing key, worked by a handle, which appears on the instrument below the dial-needle. The turning of this handle in one direction or the other gives rise to a current of electricity from the battery, which passes through the instruments of both receiver and sender. The attention of the receiver is called by the preliminary sounding of an electric bell. The *electro-magnetic* instrument of Professor Morse is an application of the second of the above properties. By means of an electro-magnet, an armature which is attracted when the magnet is temporarily magnetized, a lever moved by the armature, and a style which moves with the lever, this instrument impresses a message in dots and dashes on a ribbon of moving paper. (See **MORSE-ALPHABET**.) Cassell's telegraph effects this end by the use of a

non-conducting ink and Bain's chemical paper. Cowper's *writing telegraph* imitates hand-writing by a pen at the receiving station being made to follow the movements of a pen at the sending station. Two wires are necessary, one of them to produce similarity of position as regards left and right displacement, the other as regards up and down displacement. Strips of paper are drawn past both pens by clock-work. In addition to the delicate *mirror* or *reflecting galvanometer* (see GALVANOMETER), which Sir W. Thomson (Lord Kelvin) invented in connection with the Atlantic telegraph, the same electrician invented a self-recording instrument, consisting of a light coil of wire, very delicately suspended in a magnetic field, the motions of which coil, when a current is passed through it, are the means by which messages are recorded. The coil is attached to a very light glass siphon in the shape of an exceedingly fine capillary tube, through which ink from a reservoir is drawn by electric attraction, the reservoir and the moving paper ribbon upon which the ink falls being oppositely electrified. The extremity of the siphon is not in contact with, but only very near the paper. When there is no current the ink traces a straight line; when the current is passing the marks or deviations constituting the letters are produced. The delicacy and rapidity of this instrument are even greater than those of the mirror galvanometer, and the siphon recorder accordingly is highly valued. Although the possibility of applying electricity to telegraphy was thought of in the latter half of the eighteenth century, the principal elements of success were wanting till the discoveries of the galvanic pile by Volta in 1800, and of electro-magnetism by Oersted in 1819, since which latter date the triumphs in electric telegraphy have been achieved. In Britain the first public introduction of telegraphy was made in 1845, and thirteen years later the submarine cable between the Old and New Worlds was successfully laid. In 1872 a really workable mode of sending simultaneously two messages in opposite directions on the same line was introduced, and it was also discovered that two messages could be sent in the same direction (duplex telegraphy). The two plans being combined formed quadruplex telegraphy, by which the message-carrying powers of the wires has been greatly multiplied.—2. A telegraphic communication; a telegram. *Trolope*.

cause or purpose of phenomena, or the end for which each has been produced.

It is a relief to us . . . to fall back on the more sober arguments of the *teleologists*, who, no doubt, cannot prove from the works of creation infinite wisdom, goodness, and power, but do prove an amount of wisdom, goodness, and power which satisfies the mind. Take for instance the . . . volume of Sir Charles Bell on 'the Hand,' and say whether it is possible to follow him through the niceties and beauty of adaptation which he demonstrates without acknowledging an inconceivable amount of ingenious contrivance and benevolent design. *Ed. Rev.*

While the explanation of the *teleologist* is untrue, it is often an obverse to the truth; for though, on the hypothesis of evolution, it is clear that things are not arranged thus or thus for the securing of special ends, it is also clear that arrangements which do secure these special ends tend continually to establish themselves—are established by the fulfilment of these ends. *H. Spencer.*

Teleology (tel'ē-ō-lō'ji), *n.* [Gr. *telos*, *telos*, an end, and *logos*, discourse.] The science or doctrine of final causes: (a) the doctrine which asserts that all things which exist were produced by an intelligent being for the end which they fulfil; the science of the ends or design for which things exist or were created. Telephone (tel'ē-fōn), *n.* [Gr. *tēle*, at a distance, and *phōnē*, sound.] In a general sense any instrument or apparatus which transmits sound beyond its natural limits of audibility; thus the speaking-tube so much used in conveying the sound of the voice from one room to another in large buildings, or a stretched cord or wire attached to vibrating membranes or discs, constitutes virtually a telephone. But the name is generally restricted to an instrument transmitting sound by means of electricity and telegraph wires. About the year 1800 the idea that sound-producing vibrations could be transmitted through a wire by means of electricity began to be recognized by several men of science. Reis of Frankfurt invented an apparatus which could reproduce at a distant station the pitch of a musical sound by means of a discontinuous current along a telegraph wire. A great step in advance was made in 1876 when Prof. Graham Bell, a Scotchman resident in America, discovered an articulating telephone which depends upon the principle of the undulating current, and by means of which the very quality of a note, and therefore conversation itself, could be reproduced at a distant station. Several varieties of telephonic apparatus are now in everyday use for intercommunication between distant places. The Bell telephone in its common form is shown

in the accompanying cut. A strong ordinary bar magnet *m* has round one of its ends a coil of fine silk-covered wire in metallic

communication with the two terminals *s s*. One of the terminals communicates through a telegraph wire with one of the terminals of the coil of a precisely similar instrument at the other station, the remaining pair of terminals being connected through the earth, or through a return wire. Just in front of the extremity of the magnet there is a thin plate of iron *p*, and in front of this again there is the mouth-piece of a speaking-tube *o*. By this last the sounds to be transmitted are collected and concentrated, and falling on the metal plate cause it to vibrate. These vibrations in their turn excite undulating electric currents which correspond exactly with the vibrations; that is, with the original sounds. The electric currents being transmitted to the receiving telephone cause corresponding vibrations in the plate or disc in it, and these reproduce to the ear the original sounds.

Telephoridae (tel'ē-for'i-dē), *n. pl.* [See TELEPHORUS.] A family of coleopterous insects of a long and narrow form, with perfect wings and elytra, found in spring upon flowers, especially those of the Umbelliferae. They are very voracious, feeding not only on other insects but on the weaker of their own kind. Among children they bear the names of *soldiers*, *sailors*, and *doctors*.

Telephorus (te-le-fō-rus), *n.* [Gr. *telos*, an end, and *phoreō*, to bear.] A genus of coleopterous insects, the type of the family *Telephoridae*.

Subsequent investigations have led to the strong suspicion that the sandstone is triassic.

Telescope (tel'ē-skōp), *n.* [Gr. *teleskopos*, far-seeing, seeing afar, from *tēle*, at a distance, and *skopēō*, to view.] 1. An optical instrument essentially consisting of a set of lenses fixed in a tube or a number of sliding tubes, by which distant objects are brought within the range of distinct, or more distinct vision. The law of action by which the telescope assists human vision is twofold, and that under all the varieties of its construction. A distant object viewed by the unaided eye is placed in the circumference of a large circle, having the eye for its centre, and consequently the angle under which it is seen is measured by the minute portion of the circumference which it occupies. Now, when the distance is great, it is found that this angle is too small to convey to the retina any sensible impression—all the light proceeding from the object is too weak to affect the optic nerve. This limit to distinct vision results from the small aperture or pupil of the eye. The telescope substitutes its large objective lens or reflector for the human eye, and consequently receives a quantity of light proportioned to its

area or surface; hence a distant point, inappreciable by the eye alone, is rendered visible by the aid of the telescope. The rays of light, after transmission or reflection, converge to a point as they at first proceeded from a point, and thus an image of the object is formed which, when viewed by the eye-piece or lens, is more or less magnified. The telescope therefore assists the eye in these two ways: it gathers up additional light, and it magnifies the object; that is to say, its image. The *refracting telescope* is constructed of lenses alone, which, by successive refractions, produce the desired effect. This instrument was formerly very cumbersome and inconvenient, inasmuch as its length had to be increased considerably with every accession of power; and though the substitution of achromatic for ordinary lenses has rendered it more portable, its construction even at the present day does not enable it to compete with the reflecting telescope as an astronomical investigator. The *reflecting telescope* is composed of specula or concave reflectors, aided by a refracting eye-piece. To this instrument we owe the most wondrous discoveries in astronomical science. The names of Newton, Gregory, Herschel, and Lord Rosse are connected with its history. The following diagrams exhibit the principles of construction and action in both

Fig. 1.

sorts of telescopes. In fig. 1, which illustrates the refracting telescope in its simplest form, A and B are two lenses of different focal lengths. Rays of light from a distant object falling upon the object-glass A are converged to a focus at C. The eye-glass B, placed at its focal distance from the point of convergence, gathers up the diverging rays and carries them parallel to the eye, magnifying the image formed at C. The magnifying power of the instrument is as A C: C B, or as the focal length of one lens to that of the other. In this construction the object is inverted by the intersection of the rays, and hence it is unsuitable for terrestrial purposes. To render the image erect a more complicated eye-piece, consisting of two additional lenses, is necessary. Fig. 2 shows

Fig. 2.

the structure of the reflecting telescope as constructed by Dr. Gregory. A B is a large speculum perforated in the centre; upon this fall the rays b, a and d, e, which are reflected to convergence at C. A smaller speculum, c, takes up the diverging rays and reflects them, slightly converging, through the aperture o, where they are received by a lens, and, after transmission, they intersect at x, and proceed to the eye-glass, whence they emerge parallel. The magnifying power of this instrument is great for its length, being as $\frac{a e \times x \times C}{e C \times x o}$.

In the telescope invented by Sir Wm. Herschel there is no second speculum, and no perforation in the centre of the larger one placed at the bottom of the tube. The latter is fixed in an inclined position so that the image formed by reflection falls near the lower side of the tube at its open end or mouth, where it is viewed directly by the eye-piece, without greatly interfering with the light. This arrangement, in the case of large reflectors, is imposed by their great weight and difficult management. Were it otherwise the ordinary construction would be preferred, the inclination of the speculum being a disadvantage. Chromatic aberration, which arises from the different refrangibilities of the various coloured rays, and leads to the formation, by a lens, of a separate image of a bright object for each colour ray, is remedied by achromatizing the

lens, that is, by constructing it of two or more lenses of different kinds of glass, so that the colours, separated by one, shall be reunited by the others. See ACHROMATIC.—2. Same as *Telescopium*.—*Prism telescope*. See TELESCOPE.

The graphic tellurium (or graphic gold) is steel-gray; but sometimes white, yellow, or lead-gray. These ores are found massive or crystallized. Tellurium is very brittle, and has a sp. gr. of 5.7–6.1. It is very fusible, and volatile at a red heat. Many *temperaments* and explanations there would have met if ever I had a notion that it (a pamphlet) should meet the public eye. *Burke.*

Articular confession . . . an imperative duty in the Church of Rome, and prescribed as such in the six articles, and in the codes published by Henry VIII., was left to each man's discretion in the new order; a judicious *temperament* which the reformers would have done well to adopt in some other points.

Hallam.

3. That individual peculiarity of physical organization by which the manner of acting, feeling, and thinking of each person is permanently affected. The ancients distinguished four temperaments, which derived their names from the fancied excess of one or other of the principal humours or fluids of the body; as, the *choleric* or bilious, from *Gr. cholé*, bile; the *phlegmatic*, from *phlegma*; the *melancholic*, from *melaina*, black; and *cholé*, bile; and the *sanguine*, from *L. sanguis*, blood. Many modern authorities have adopted a classification indicative of the fulness of habit and relative activity of the nutritive functions, and cerebro-spinal activity, employing the terms *sanguineous*, *nervous*, *nervo-sanguineous*, *sanguineo-nervous*, *lymphatic*, and *phlegmatic*. Dr. Cullen and others admit of only two temperaments, the sanguine and the melancholic, considering the phlegmatic a degree of the sanguine, and the choleric of the melancholic; and many of the so-called temperaments, as the bilious, melancholic, and lymphatic have been looked upon merely as departures from health, the result of imperfect development, incorrect habits, bad nutrition, and inactive functions of the body, which may be modified or removed by corrected habits, regimen, or medical treatment.—4. † Condition as to heat or cold; temperature. 'In proportion to the fertility of the soil and the *temperament* of the climate.' *Cook.*

Bodies are denominated hot or cold in proportion to the present *temperament* of our body to which they are applied. *Locke.*

5. In *music*, a certain adjustment or regulation of the tones or intervals of the scale of fixed-toned instruments, as the organ, piano, and the like, with the view of removing an apparent imperfection, and fitting the scale for use in all keys without offence to the ear. The intervals between the notes of the natural scale are by no means equal. Thus, sup-

posing the perfect octave to be divided into fifty-three equal parts, or *commas* as they are technically called, and taking C as the key-note or tonic, the intervals between the notes would be made up as follows: C to D, 9 commas; D to E, 8; E to F, 5; F to G, 9; G to A, 8; A to B, 9; B to C, 5. We have here three species of intervals, of which those represented by 9 are called major tones; those by 8, minor tones, and those by 5, major semitones. A fixed-toned instrument tuned on this principle would fully satisfy the ear with the correctness of its tones and the richness of its concords while the key of C was adhered to. But if we start, say, from D as a key-note, the proportions of the scale, or the sequence of the major and minor tones and of the semitones, are destroyed. D to E would form a tolerable, though not absolutely correct second, but the third and seventh of the scale would be entirely wrong. Were the major and minor tones equal, and each semitone exactly half a tone, the insertion of a note between each full tone, exactly dividing the intervals between them, would give an ideally symmetrical scale, and it would be immaterial where the scale began, as each of the twelve notes would be available as a key-note. Now, though such an equality is contrary to the principles of harmonics, an adjustment or arrangement of the sounds of fixed-toned instruments founded on it gives practically no offence unless to the critical ear. In what is termed *equal* or *even temperament*, which is now, theoretically at least, adopted for all pianos, organs, harmoniums, &c., the twelve semitones are all adjusted so as to stand at intervals of the same length, and thus no advantage is given to one key over another. In the *unequal* or *vulgar temperament*, formerly adopted for organs, some popular keys, as B \flat , F, C, G, and D, were favoured at the expense of the rest, that is, the true intervals of the normal or natural scale were pretty closely adhered to; but the harsh fifths and thirds (the 'Wolf tones' of musicians) occurring in the keys written in several flats or sharps caused this system to be abandoned. The different characters of the various keys recognized on most fixed-toned instruments could have no existence were equal temperament absolutely adhered to, and are due to the fact that some discrimination is still practically used in favour of certain popular keys, though not to such an extent as to injure very sensibly the effect of keys less favoured. The only instruments of orchestral importance capable of producing just intonation, or of being played in perfect tune, are those of the violin family, which in this respect approach the perfection of the human voice; and were not a habit of incorrect intonation too often acquired by performing to the accompaniment of tempered instruments, the skillful singer or violinist could produce his notes in true key relationship through the most intricate modulations or changes of key.

Moderation; the observance of moderation; temperateness; particularly, (a) habitual moderation in regard to the indulgence of the natural appetites and passions; restrained or moderate indulgence; abstinence from all violence or excess, from improper indulgence, or from the use of anything injurious to moral or physical well-being; sobriety; as, *temperance* in eating and drinking; *temperance* in the indulgence of joy or mirth.

When it (virtue) ruleth and ordereth our lust or concupiscence, limiting out a certain measure, and lawful proportion of time unto pleasures, it is called *temperance*. *Holland.*

If thou wilt observe
The rule of Not too much; by *temperance* hold

So may'st thou live, till, like ripe fruit thou drop
Into thy mother's lap. *Milton.*

Temperance permits us to take meat and drink not only as physic for hunger and thirst, but also as an innocent cordial and food for the evils of life, or even sometimes reason not refusing that liberty, merely as a matter of pleasure. It only confines us to such kinds, quantities, and seasons as may best consist with our health, the use of our faculties, our fortune, &c. *Wollaston.*

(b) Patience; calmness; sedateness; moderation of passion.

He calm'd his wrath with goodly *temperance*. *Spenser.*

2. † Temperature.

It (the island) must needs be of subtle and delicate *temperance*. *Shak.*

The word is frequently used adjectively; as, the *temperance* movement; a *temperance* society; a *temperance* hotel; a *temperance* lecture, &c.—*Temperance hotel*, a hotel in which no intoxicant liquors are supplied to the guests.—*Temperance society*, an association formed for the purpose of repressing drunkenness, and banishing it from society. The basis on which these associations have generally been formed has been that of an engagement on the part of each member to abstain from the habitual and improper use or indulgence in intoxicating liquors. As the most strictly limited use of intoxicants as beverages is condemned by many social reformers as physically and mentally injurious, this name has been applied to, or assumed by, associations which are more correctly designated total abstinence or teetotal societies.

5. † Moderate degree of atmospheric heat; temperateness of climate. 'If instead of this variation of heat we suppose an equality or constant *temperature* of it before the deluge.' *Woodward.*—6. The state of a body with regard to heat; the degree or intensity of the heat effects of a body; the thermal state of a body considered with reference to its power of communicating heat to other bodies. When two bodies are in contact, and the flow of heat from the one body to the other is equal—that is, when by contact neither is heated or cooled by the other—they are said to be of the same *temperature*. Two bodies may have the same *temperature* and yet contain very different quantities of heat per unit of mass, so that the *temperature* of a body is not a measure of its heat. If heat be considered as a motion of the molecules of a body, *temperature* may be considered a measure of the velocities of the molecules. When we speak of a body having a 'high' or a 'low *temperature*' it is implied that the condition of heat in the body may be compared with some standard. The means of such comparison is the thermometer, and the most convenient standard condition is apparently that of a body at the melting-point of ice, which is marked on the Centigrade thermometer scale and on Réaumur's as zero. See THERMOMETER.—7. *Animal temperature*, the degree or intensity of heat of animal bodies. This varies considerably with the classes of animals; thus the average *temperature* of mammals is stated at 101° Fahrenheit; that of birds, at 107°. Below mammals and birds animals are termed 'cold-blooded,' this term meaning in its strictly physiological sense that the *temperature* is usually that of the medium in which they live, and that it varies with that of the surrounding medium. The average normal *temperature* of the human adult is about 98°-5, but in some cases of disease, as fevers, it may rise to 106°, 107°, or even as high as 112°, while in other cases, as morbus carculus and Asiatic cholera, it may fall as low as 77°-5.—*Mean temperature*, a mean of all the atmospheric *temperatures* observed at a given place or under certain circumstances at regular intervals during a certain space of time. The mean annual *temperature* of any place is obtained by taking a mean of all the *temperatures* indicated by the thermometer each day throughout the year. The *temperature* of a place depends not only on its latitude, but also on its elevation above the level of the sea, and various other local causes, such as the nature of the soil, the prevailing winds, the quantity of moisture, the electric state of the atmosphere, and the physical character of the adjacent countries and seas. But no cause has such an effect in lowering the *temperature* of a place as elevation above the level of the sea; and hence near the equator there are mountains which, owing to their great elevation, are covered with snow all the year round. (See SNOW-LINE.) The *temperature* of the sea is more uniform and moderate than that of the land.

Tempered (tem'pərd), *a.* Having a certain disposition or temper; disposed: often used in composition; as, a well-*tempered*, good-*tempered*, or bad-*tempered* man.

To stop his ears against admonishment? *Shak.*

—*Tempered glass*. See under GLASS.

Tempering (tem'pə-ring), *n.* The process of giving the requisite degree of hardness or softness to a substance, as to iron or steel; especially, the process of giving to steel the different degrees of hardness required for the various purposes to which it is applied. The process essentially consists in plunging the steel when red-hot into cold water or other liquid to give an excess of hardness, and then gradually reheating it until the hardness is reduced or brought down to the required degree. The excellence of all cutting steel instruments depends on the degree of temper given to them. Different degrees of temper are indicated by different colours which the steel

assumes. Thus steel heated to 450°, and suddenly cooled, assumes a pale straw colour, and is employed for making razors and surgical instruments. See STEEL.

Tempest (tem'pest), *n.* [O. Fr. *tempeste*, Mod. Fr. *tempête*, from L. *tempestas*, time, especially time with respect to its physical qualities, weather, and specifically, bad weather, a storm or tempest, from *tempus*, time. See TEMPEL.] 1. Templar (tem'plār), *n.* 1. One of a religious

military order first established at Jerusalem in favour of pilgrims travelling to the Holy Land. The order originated with some persons who, in 1118, devoted themselves to the service of God, promising to live in perpetual chastity, obedience, and poverty, after the manner of canons. Baldwin II, king of Jerusalem, bestowed on them their first place of residence in the city, close to the Temple, and an additional building was acquired from the abbot and canons of the church and convent of the Temple, whence the order received the name of the 'poor soldiers of the Temple,' afterwards converted into *Templars*, or *Knights Templars*. The knights wore a white cloak adorned with a red cross of eight points (the

Mattese cross) on the left shoulder. In 1223 this order was confirmed in the Council of Troyes, and subjected to a rule of discipline. It flourished, became immensely rich and powerful, and its members became so arrogant and luxurious that the order was suppressed by the Council of Vienne in 1312.—2. An edifice dedicated to the service of some deity or deities, and connected with some pagan system of worship; originally, an edifice erected for some Roman deity; but the term is generally applied to such edifices among the Greeks, Egyptians, and other ancient nations as well as to structures serving the same purpose among modern heathen peoples. The most celebrated and imposing of the ancient temples were those of the Greeks, such as that of Artemis or Diana at Ephesus, that of Zeus Olympus in Athens, and that of Apollo at Delphi. The form most generally given to the ancient temples was that of a rectangle, but sometimes the construction was circular.

Vitruvius divides temples into eight kinds, according to the arrangement of their columns, viz. temples in *antis* (see ANTA), *prostyle*, *amphiprostyle*, *peripteral*, *dipteral*, *pseudodipteral*, *hypæthral*, and *monopteral*. (See these terms.) In regard to intercolumniation, they are farther distinguished into *pycnostyle*, *systyle*, *eustyle*, *diastyle*, and *aræostyle*, and to the number of columns in the portico, *tetrastyle*, *hexastyle*, *octastyle*, and *decastyle*. The third, the largest and most magnificent of the three, was begun by Herod the Great in 20 B.C., and was completely destroyed at the capture of Jerusalem by the Romans, 70 A.D.—3.
